Executive summary

1. This report creates a national standard for the use of conscious sedation in the delivery of dental care. The standards apply to all who practise conscious sedation techniques, whether they are dentists, doctors, nurses or dental care professionals.

2. Conscious sedation is an important modality that forms one strand of the delivery of dental care to patients who have significant anxiety. This document describes the clinical techniques that are available for conscious sedation in dentistry and the appropriate environments for their delivery.

3. The report defines the age of a child as being an individual of under 12 years in respect of the delivery of conscious sedation. It is recognised that a numerical definition has limitations when considering both physical and mental maturity. The clinical team and facilities required for the dental treatment of younger patients under conscious sedation are defined in this report. It is recognised that significant development and investment will be required to meet these requirements.

4. Dental care is provided for the benefit of our patients. This report makes recommendations about ensuring that they receive the best care, which requires that the healthcare team makes available both verbal and written information of high quality in a form that is easily assimilated by patients, their parents or carers.

5. Patients have the right to expect a high quality service to meet their dental needs. This can only be achieved through robust, validated education and training of the entire dental team. Educational or training courses that teach clinical techniques preparing individuals for independent practice must include supervised clinical practice. The requirement for high quality education underpins the report.

6. The requirements for high quality education, which include supervised clinical practice, may limit the number of providers that are able to provide training courses.

7. Sedation services must demonstrate a high level of safety and a continuing improvement in quality. The use of appropriate audit tools to review clinical outcomes is an essential component of good clinical practice. Careful and reflective use of such data will enhance patient safety and improve the quality of care.

8. It is recommended that a system for reporting adverse events in the delivery of conscious sedation in dentistry be developed for those working in independent practice. This should parallel systems currently used in National Health Service (NHS) institutions.

9. The report recognises the need for healthcare professionals not only to gain knowledge and skills but also to maintain and further develop them. Individuals who wish to practise conscious sedation must undergo regular continuing education in the techniques that they use. Those using a technique of conscious sedation infrequently should consider whether it is in the best interests of patients for them to continue to use it. (FAQ 10).

10. All centres providing conscious sedation for the delivery of dental care should be inspected to determine that the necessary standards are in place. This is currently the responsibility of the relevant agencies in each country in the UK.

11. It is recognised that some of the recommendations of this report will have far-reaching consequences. Implementation may have significant implications for providers and for those who commission dental clinical services but safety of patients is our priority.

The Intercollegiate Advisory Committee for Sedation in Dentistry (IACSD)\(^1\) defines standards for the provision of conscious sedation in dentistry in the UK.

IACSD reviewed the 2015 Standards on 20 June 2019. The committee decided that, in the absence of new clinical evidence or safety issues, it was not necessary to make any substantial changes to the original guidance. However, feedback suggested it would be helpful to incorporate and reference the IACSD frequently asked questions on the FDS RCSEng website. There are also a small number of minor typographical changes. The committee agreed that a detailed review and update of the IACSD Standards should be considered by the end of 2022.

This publication creates a national standard for conscious sedation in dentistry and replaces the previous documents Conscious Sedation in the Provision of Dental Care (2003),\(^2\) Standards for Conscious Sedation in Dentistry (2007)\(^3\) and Conscious Sedation in Dentistry (2012).\(^4\)

It is to be read in conjunction with Safe Sedation Practice for Healthcare Procedures published by the Academy of Medical Royal Colleges in October 2013\(^5\), Sedation in Children And Young People published by the National Institute for Health and Care Excellence (NICE) in December 2010\(^6\) and Conscious Sedation in Dentistry: Dental Clinical Guidance, 3rd Edn, SDCEP 2017\(^7\). There are differences in laws, regulations, ethical guidance and governance between different countries in the UK and Ireland; this report describes best practice but it is incumbent on individuals to be aware of the laws and regulations as they pertain in the country in which they work.

Where conscious sedation is used to facilitate dental treatment, it is essential that it is provided to the highest possible standards. Quality standards coupled with the specific needs of the patient have correctly received increased emphasis and there is an imperative for the best possible quality of care. This can only be achieved through education and training of the workforce to defined standards and by ensuring that the environment in which care is delivered meets similarly defined standards. Clinical skills can only be maintained through rigorous and ongoing review of the care that has been provided as well as the continual pursuit of knowledge and skills. Robust education and training underpins safe and effective dental care for patients requiring dental sedation, and this therefore forms a significant element of this report.

Optimal care is patient-centred and focuses on the needs of the individual. For techniques of conscious sedation in dentistry, this document describes the methods available and the appropriate environment for their delivery. The foundation for this report is high quality training and robust assessment of outcomes. High quality care recognises the need for audit and reflection together with the requirement that skills once gained are subject to interval re-assessment and evaluation.

The implementation of this report is essential for the provision of clinical services that ensure appropriate management and patient safety. The first part of the report provides core information. Each heading is then expanded into the later sections to give essential details covering the delivery of dental care using conscious sedation. The clinical standards, training and assessments described in this document apply to all dentists, doctors and healthcare professionals who provide or directly support sedation for the delivery of dental care. (FAQ 1, 2, 11).
Introduction

The effective management of anxiety and pain is an essential part of the delivery of dental care. Behavioural management, the use of local analgesia and methods of conscious sedation are all central components of care for patients who are frequently anxious about receiving dental treatment. Conscious sedation, provided when appropriate, in a skilled manner and in the correct environment, is widely used, valuable and effective.

There is a continuum from the fully conscious state to the unconscious when all protective reflexes have been lost. The publication from the Academy of Medical Royal Colleges, *Safe Sedation Practice for Healthcare Procedures*, gives the definitions of sedation and describes clearly this continuum from minimal sedation through to general anaesthesia, which is accompanied by increasing depression of the physiological systems. This increases the likelihood of adverse events and an increasing depth of sedation is accompanied by an escalation in the competency required to ensure safe sedation practice.

This document addresses conscious sedation, which is defined as:

...a technique in which the use of a drug or drugs produces a state of depression of the central nervous system enabling treatment to be carried out, but during which verbal contact with the patient is maintained throughout the period of sedation. The drugs and techniques used to provide conscious sedation for dental treatment should carry a margin of safety wide enough to render loss of consciousness unlikely.

The level of sedation must be such that the patient remains conscious and is able to both understand and respond to verbal commands either alone or accompanied by a light tactile stimulus.

In the case of individuals who are unable to respond to verbal contact even when fully conscious, the normal method used for communicating with them must be maintained.
Options for care

There is a range of modalities that can assist in the management of anxiety to facilitate the provision of high quality dental care. Conscious sedation is just one option for the control of anxiety, and it is essential that all options are considered and explained to the patient (and, where appropriate, the carer) before a decision is reached.

This is based on establishing the best patient management and involves provision of information, counselling and reassurance as primary measures of anxiety control.

When pain control is required for a dental procedure to be carried out under conscious sedation, appropriate use of local analgesia is also required. Conscious sedation is not a substitute for effective behaviour management and local analgesia.

Behaviour management, local analgesia or general anaesthesia may each have a role in facilitating patient care. A practitioner must therefore make a careful, thorough assessment of the patient and his or her needs before deciding that the use of conscious sedation is indicated. The decision to use a particular approach must be based on a full assessment in respect of healthcare history, psychological needs and overall management. The use of conscious sedation may be indicated for special care patients, certain medical indications or difficult clinical situations. However, conscious sedation is designed only to facilitate the delivery of dental care. It is essential that patients who are to be managed using conscious sedation are assessed carefully and also receive a dental assessment. The treatment plan must be agreed with the patient and any carer; ideally, this should be done in advance of the procedure.

The patient should receive the treatment most appropriate for his or her oral condition and circumstances. Care pathways are seen as encouraging good practice and, where available, should be followed.

The age when an individual ceases to be a child in respect of the provision of dental care under sedation cannot be defined numerically. In relation to conscious sedation, the description of the Resuscitation Council (UK) is pertinent where a child is defined as being between 1 year of age and puberty. The lower end of the range for the onset of puberty is considered to be 12 years but may be earlier or later when physical maturity is considered.

Patients who have not reached puberty are physiologically immature and will require a sedation team member with paediatric resuscitation skills. Providers and commissioners will need to consider this when planning services for this group of patients.

Any child under 12 years of age with complex oral needs or any child under 12 years who cannot be managed with either:

a) behavioural management techniques/local analgesia or
b) local analgesia plus inhalation sedation

with the responsible dental practitioner having received appropriate training should be referred to a team having skills equivalent to those expected of a specialist/consultant in paediatric dentistry and a consultant in anaesthesia competent in sedation for dentistry for assessment and treatment in
a facility equivalent to an NHS Acute Trust in England.* This would include care provided by a managed clinical network or a recognised care pathway.

Any young person aged 12–16 years with complex oral needs or any young person aged 12–16 years who cannot be managed with either:

a) behavioural management techniques/local analgesia or

b) local analgesia plus inhalation sedation or
c) local analgesia plus midazolam (all routes)

with the responsible dental practitioner having received appropriate training should be referred to a team having skills equivalent to those expected of a specialist/consultant in paediatric dentistry and a consultant in anaesthesia competent in sedation for dentistry for assessment and treatment in a facility equivalent to an NHS Acute Trust in England.* This would include care provided by a managed clinical network or a recognised care pathway. (FAQ 18, 20, 21).

This report focuses on conscious sedation in dentistry, which is an adjunct to the delivery of oral healthcare for patients. Appropriate assessment and proper dental treatment planning for each patient are mandatory. This is important for all patients and symptomatic dental care is not in any patient's long-term best interests. In particular, where dental needs are complex, the involvement of colleagues with additional skills is always likely to be beneficial and is sometimes essential.

There is a range of options available to support clinicians and patients in deciding on the best management and care of patients who are unable to receive routine care. Selection of the most appropriate pathway must be decided by patient need and some of these may be time-specific.

Some of the issues involved are anxiety, a pronounced gag reflex, a traumatic procedure, the level of patient co-operation, the nature of the clinical care required and the time needed to deliver treatment.

The options should be considered carefully and the selection at any one point in time will depend on a range of factors relating to the patient, for example the nature and urgency of care. The chosen option must be justified in the clinical records.

Figure 1 shows the major options for managing anxiety. Patients may require different support services at different points in their dental care, which are also dependent on the complexity of the treatment. Consideration should therefore also be given to the most appropriate modality for the patient next time dental treatment is to be carried out and whether this will require a different provider.

Where there are particular patient needs for the management of anxiety or other aspects that affect the individual's ability to receive dental treatment (e.g. a pronounced gag reflex), referral to another provider may be in the patient's best interests. When referring a patient, clear referrals must be made, the guidance described by the Dental Sedation Teachers Group should be followed and the responsibilities described by the General Dental Council (GDC) in the UK must be met.11

---

*Scotland: an NHS Board; Wales: a Health Board; Northern Ireland: a Health and Social Care Trust

---

**Figure 1** The options for managing dental anxiety.
Preparation for sedation

Consent for treatment

The patient requires clear and comprehensive information regarding the proposed treatment as part of the process of gaining valid consent. Valid consent is necessary for all patients receiving dental care under conscious sedation and this must be confirmed in writing. Consent should follow the principles set out in the GDC’s Standards for the Dental Team. Consent is a complex process, and different laws and regulations apply at different ages in different countries in the UK. Practitioners must be aware of the laws that apply in their own country.

Patients and, when appropriate, those with parental responsibility and carers require information to be provided in a way that can be understood before the process of valid consent can be completed. Patients who are already sedated cannot be regarded as competent to take valid decisions regarding consent for treatment. Consent for dental treatment attempted under these circumstances is not valid.

Consent obtained on the day of treatment is not appropriate except when immediate treatment is in the best interests of the patient. Consent obtained prior to the day of treatment must also be re-confirmed on the actual day of treatment.

The capacity to consent depends on a person’s ability to understand and voluntarily weigh up options rather than age. A person is unable to make a decision if they cannot do one or more of the following:

- understand the information given to them that is relevant to the decision
- retain that information long enough to be able to make the decision
- use or weigh up the information as part of the decision-making process
- communicate their decision – this could be by talking or using sign language and includes simple muscle movements such as blinking an eye or squeezing a hand.

The Mental Capacity Act 2005 states that if a person lacks mental capacity to make a particular decision, then whoever is making that decision or taking any action on that person’s behalf must do this in the person’s best interests. For the purposes of consent, ‘children’ refers to people aged below 16 years and ‘young people’ refers to people aged 16–17 years. All people aged 16 years of age and over are presumed in law to have the capacity to consent to treatment unless there is evidence to the contrary.

Children aged under 16 can be legally competent if they have sufficient understanding and maturity to enable them to understand fully what is proposed. If the child is deemed not legally competent, consent will need to be obtained from someone with parental responsibility, unless it is an emergency.

Families of children under the age of 16 years should be involved in decisions about their care unless there is a very good reason for not doing so. However, if a competent child under 16 is insistent that their family should not be involved, their right to confidentiality must be respected, unless such an approach would put the child at serious risk of harm.
Written information for adult and child patients, those with parental responsibility, carers and escorts must be supplied. This is to be used in conjunction with the clinical pre-operative assessment and face-to-face discussions and explanation. It must include the range of techniques appropriate for both the relief of anxiety and the behaviour management appropriate for the dental treatment needs of the individual.

Adult patients will receive written information at the pre-operative visit. For child patients receiving sedation, information in written form for both the child and those with parental responsibility and carers will be supplied at the time of the clinical assessment.

Written information about the sedation procedures available and the specific technique planned for the adult or child patient will need to conform to the local health provider’s patient information policy. This will be subject to local stakeholder consultation and audit. Written patient information must be provided sufficiently in advance of the procedure to allow patients and carers time to absorb the information and comply with the instructions given.

Information regarding the sedation technique should contain a description of the sedation procedure that has been suggested and recommended as the most appropriate management technique for the individual patient, including its benefits, risks and alternatives. It should take into account the subjective feelings expected to be experienced by the patient during and after the sedation. The information must also include relevant contact details of the care provider as well as the out-of-hours contact details for emergency advice and services.

Instructions for the pre- and post-operative periods must be suitable for each age group of patients and their escorts and carers.

**Adults and young people**

For adult patients and young people, clear instructions must be provided regarding the practical arrangements to be followed pre- and post-operatively. These will include the responsibilities of the escort pre- and post-operatively. The patient must also receive a separate information sheet describing the responsibilities of the escort, which the patient must give to the escort. Practitioners should bear in mind the limitations of patients and escorts in following such instructions.

**Children**

For those with parental responsibility for patients under 16 years of age, the information must include preparation of the child prior to the appointment as well as post-operative instructions for the sedation provided and the dental treatment performed.

For children, separate age appropriate information regarding the sedation procedure should also be provided. For very young children, it should be remembered that this may need to be in a very simplified form, and that written information must be used in conjunction with (and not instead of) a face-to-face explanation and discussion of the sedation technique with the child or young person involved.

Written information forms only a part of the overall psychological preparation of an adult or child who is to receive dental care in combination with sedation. Psychological preparation in the form of cognitive behavioural therapy, distraction, guided imagery, hypnosis, demonstration play therapy and music therapy may form part of the preparation. The techniques used to reduce fear and anxiety will need to match the needs of the individual patient to facilitate a successful treatment outcome.

Further documents providing examples of intercollegiate guidance on content and style are presented in Section 4: Patient information and in Appendix 3.

The information provided should reflect the guidance given to the patient. There is a requirement for clear and accurate information to be provided for patients, those with parental responsibility, carers and escorts. Written patient information should be prepared in line with NHS guidance reflecting the needs of the different patient groups using the service, for example patients with learning disabilities or where English is not the first language.
The need for fasting prior to dental treatment under conscious sedation continues to be the subject of significant discussion. The Academy of Medical Royal Colleges publication Safe Sedation Practice for Healthcare Procedures, with which this report is aligned, devotes a section to fasting, which is quoted in full:

‘Pre-operative fasting for sedation is controversial and considered unnecessary by some authorities within dentistry and emergency medicine for conscious sedation.’ Airway reflexes are assumed to be maintained during moderate and minimal sedation, and lost during general anaesthesia. It is not clear where the point of loss of reflexes lies, or if such a point exists. The argument is that using minimal and moderate sedation, airway reflexes are maintained but this does not consider the potential for inadvertent over-sedation and the loss of protective airway reflexes. In the United Kingdom the loss of verbal communication/deep sedation is deemed to require the same level of care as general anaesthesia, and many practitioners therefore follow accepted fasting guidance.

Guidance from NICE on sedation of children recommends fasting before sedation unless the sedation is limited to:

- minimal sedation
- sedation with nitrous oxide (in oxygen)
- moderate sedation during which the child or young person will maintain verbal contact with the healthcare professional

For elective procedures using any sedation other than the above (and specifically for deep sedation and moderate sedation during which the child or young person might not maintain verbal contact with the healthcare professional) the 2-4-6 fasting rule applies (that is, two hours for clear fluids, four hours for breast milk and six hours for solids).

For an emergency procedure in a child or young person who has not fasted, the decision to proceed with sedation should be based on the urgency of the procedure and the target depth of sedation.

Careful consideration on a case-by-case basis of the patient’s presenting condition, co-morbidities, the nature of the procedure and the limitations of the environment, is important to evaluate the risks of aspiration.

Clinicians who choose to sedate patients without fasting should be prepared to justify this choice.’

Advice on eating and drinking prior to the appointment for treatment under any form of conscious sedation should be given to the patient verbally and in writing at the assessment visit. This must be recorded in the patient’s clinical records.
Clinical environment for sedation

The physical environment, supporting facilities and equipment must be appropriate for the delivery of dental care under sedation. All providers of conscious sedation services are responsible for ensuring that the environment in which care is delivered is appropriate for the needs and safety of patients, carers and staff. All centres providing conscious sedation for the delivery of dental care should be inspected to determine that the necessary standards are in place.

The correct equipment and facilities for the delivery of the type of care required must be used, and must conform to accepted standards for health and safety. All appropriate equipment must be available in working order when sedation is being provided and during recovery. Equipment must be maintained in accordance with the schedule described by the manufacturers. Records of the maintenance of equipment must be retained and made available for subsequent formal inspections.

The clinical setting must permit access for the emergency services and the transfer of the patient.

Further information on the requirements for the premises and the equipment required together with a patient pathway may be referenced in the form of a checklist. An example of this will be found at https://www.SAAD.org.uk/documents (FAQ 19).
Nature of the clinical team for sedation

Table 1 in Section 2: Clinical sedation techniques describes the clinical team required for each conscious sedation technique. All members of the care team must have the relevant knowledge and skills for the technique being used, as defined by their scope of practice and competencies.

Clinical skills are underpinned by validated education and training while knowledge and continuing competence must be maintained through appropriate continuing professional development.
Techniques of sedation

There is a range of techniques of conscious sedation available. The selection of a technique must be appropriate for the individual patient and not chosen simply for operator or sedationist convenience or at the insistence of a third party. The practitioner providing the sedation must be trained and competent in the technique used, and each individual in the team caring for the patient must also have the necessary validated skills.

Essential principles of safe sedation practice

1. The use of sedative drugs does not negate the need for good communication skills and a sympathetic manner.

2. No one technique is suitable for all patients. However, adopting the principle of minimum intervention, the simplest and safest technique that is likely to be effective, based on robust patient assessment and clinical need, should be used.

3. Titrating a drug/drugs to effect is critical to safely achieving a recognised sedation endpoint (i.e. conscious sedation) and avoiding inadvertent oversedation. The initial dose must have taken full effect before an additional dose is given. Safe sedation demands knowledge for each drug of time of onset, peak effect and duration of action.

4. While over-sedation must be avoided, under-sedation will have an adverse effect on the patient and the delivery of effective treatment.

5. As a general rule, single drugs are easier to titrate to effect and safer than sequential administration of two or more drugs. Drugs used in combination may produce synergistic effects, have differing times to onset and peak effect, and may be unpredictable or difficult to titrate to effect. Safety margins may be narrowed, increasing the likelihood of overdose, loss of consciousness, respiratory depression and the need for airway interventions. Benzodiazepines may be up to eight times more potent after prior administration of opioid and so must be titrated with care.

6. Anaesthetic drugs and infusions (e.g. propofol) used as sedative agents have narrower therapeutic indices and reduced margins of safety, potentially increasing the likelihood of adverse events.

7. Multiple/anaesthetic drug techniques should only be considered by those skilled in their use, where there is clear clinical justification, after having excluded simple techniques, and must only be used in an approved setting where team skills are sufficient to resuscitate and stabilise a patient until the arrival of the emergency services.
Specific techniques

The essential aspects of each technique are listed below and more detailed information is provided in Section 2: Clinical sedation techniques. For all conscious sedation techniques other than inhalation sedation with nitrous oxide/oxygen, competence in cannulation is mandatory.

Oral pre-medication and oral sedation

There is a difference between pre-medication and oral sedation. Oral pre-medication involves the self-administration of a small dose of an oral sedative to alleviate anxiety. This usually takes place outwith the dental practice. Subsequent doses of sedative drugs may need to be reduced accordingly. Oral sedation involves the administration of a much larger dose of an oral sedative at the dental practice. The monitoring and discharge requirements for oral sedation are the same as for intravenous sedation. Oral sedation must only be administered in the place where the dental treatment is provided and must only be carried out by practitioners who are already competent in intravenous sedation.

Nitrous oxide/oxygen sedation (inhalation sedation): A titrated dose of nitrous oxide in oxygen is the first choice inhalation sedation technique.

Midazolam (intravenous sedation): A titrated intravenous dose of midazolam is usually the first choice intravenous sedation technique.

Midazolam (oral sedation): Midazolam is now considered the first choice agent for oral sedation.

Oral techniques are not titratable and should only be used when titratable sedation techniques are inappropriate.

Temazepam (oral sedation): Historically, temazepam was the first choice oral sedative for use in dentistry. Its use has been largely superseded by midazolam. Oral techniques are not titratable and should only be used when titratable sedation techniques are inappropriate.

Midazolam (intranasal sedation): Intranasal sedation is one of a group of routes of administration referred to as transmucosal sedation. These techniques have become more popular in recent years, especially in special care dentistry. As with oral sedation, these techniques are not titratable and should only be used when titratable sedation techniques are inappropriate.

Opioid and midazolam (intravenous sedation): This is an intravenous technique where a single small dose of an opioid (usually fentanyl) is followed by a titrated dose of midazolam. It is used for patients for whom midazolam alone does not produce adequate anxiolysis.

Ketamine (oral/intravenous sedation): Ketamine is increasingly being used for paediatric dental conscious sedation. However, until more evidence on its use and safety is published, it is difficult to offer detailed guidance.

Midazolam (patient-controlled sedation): The IACSD is unaware of anyone currently using patient-controlled midazolam for conscious sedation in dentistry in the UK but it is included here for completeness.

Propofol (patient-controlled sedation): There have been a number of studies published in which patient-controlled propofol conscious sedation has been examined. The availability of safe and reliable, licensed delivery systems needs to be investigated.

Propofol (target-controlled infusion sedation): Target-controlled infusions of propofol are widely used for sedation in many medical and dental fields. These techniques require the presence of a dedicated sedationist. They are particularly useful for both very long and very short procedures as well as for patients who have developed a tolerance to benzodiazepines.
**Midazolam and propofol (intravenous sedation):** This technique is particularly useful for longer dental procedures. The sedation is induced with a titrated dose of midazolam and then maintained with a continuous infusion of propofol. As with propofol administered alone, this technique requires a dedicated sedationist.

**Sevoflurane (inhalation sedation):** Techniques involving the use of a titrated dose of sevoflurane in oxygen or in nitrous oxide and oxygen have been studied in paediatric dental patients. These techniques appear to be more effective than a titrated dose of nitrous oxide in oxygen but have yet to achieve widespread acceptance. A dedicated sedationist is required for these techniques owing to the lack of availability of a simple delivery system suitable for use in a dental environment.
Peri-operative care

Monitoring

The principles of monitoring are described in *Safe Sedation Practice for Healthcare Procedures*. During conscious sedation the patient responds to verbal commands. Cognitive function and physical co-ordination may be impaired but airway reflexes, ventilatory and cardiovascular functions are usually unaffected. The sedationist or another appropriate person who has capability within his or her scope of practice must monitor the patient throughout the procedure and will wish to confirm at regular intervals that the patient is conscious. If this level of sedation is exceeded, the team caring for the patient must have the appropriate skills to manage the situation.

As well as monitoring the depth of sedation and patient comfort, it is vital to provide clinical monitoring and electronic and mechanical monitoring appropriate to the technique and the medical status of the patient. There must be a written contemporaneous record of the monitoring of the patient that is in accordance with the clinical sedation technique used.

Clinical and instrumental monitoring relevant to the patient’s medical status and the clinical setting must be used. For inhalation sedation with nitrous oxide, clinical monitoring will usually suffice. As a minimum for all other techniques, monitoring should include pulse oximetry as well as non-invasive blood pressure monitoring pre-operatively, at appropriate intervals during the procedure and post-operatively. All members of the clinical team must be capable of monitoring the condition of the patient. The monitoring requirements specific to each technique are recorded in Table 2 in [Section 3: Peri-operative care](FAQ 24).

Complications

Conscious sedation delivered appropriately by trained, competent individuals in a suitable environment can deliver benefits for patients. However, there can be risks, of which the patient should be made aware, and complications that the clinical team needs to manage.

‘Rescue’ is the term used to describe the management of adverse events that may occur during the delivery of dental treatment under conscious sedation. It is essential that the team delivering care is able to recognise such adverse events and manage them appropriately and safely. These events may be medical, dental or related to the sedation.

The dentist’s responsibility is to manage complications resultant from medical or dental emergencies. The sedationist, who may be a dentist, doctor or dental hygienist and therapist, must be able to manage any complication arising from the sedation itself and from medical emergencies.

The dentist, dental hygienist and therapist, sedationist and dental nurse must be competent
Recovery, discharge and aftercare

The presence of a suitable third party to take responsibility for the patient at the time of discharge is an essential requirement for sedation using anything other than inhalation sedation with nitrous oxide/oxygen in adults. Children under 16 years of age require an escort for inhalation sedation.

For all other forms of sedation for adults and children, an escort is required. If the attendance of an escort cannot be assured, treatment under sedation must not be provided.

Recovery from sedation remains the responsibility of the care team until the patient can be discharged into the care of the responsible adult escort. Recovery is a progression from the peak effects of the sedation.

During recovery, the patient must be supervised; a trained member of the dental team must be responsible for the patient and monitor the individual throughout this period. See Table 2 in Section 2: Clinical sedation techniques. All necessary equipment and drugs must be available to support recovery and to manage any complications that may arise.

The decision to discharge the patient is the responsibility of the sedationist, with each patient being assessed on an individual basis. Verbal and written instructions for the post-operative period must be provided for both the patient and the responsible adult escort. Examples of the written instructions are provided in Section 4: Patient information and in Appendix 3. They must include the post-operative risks, pain control and possible post-operative complications together with the aftercare arrangements and emergency contacts.

Patients should be formally assessed for suitability for discharge from the clinical area where sedation has taken place. Discharge criteria include:

1. The patient is orientated in time, place and person.
2. Vital signs are stable and within normal limits for the patient. Respiratory status is not compromised.
3. Pain and discomfort have been addressed.
4. Where relevant, haemostasis has been observed.
5. The cannula, where inserted, has been removed.
6. The responsible escort is present and arrangements have been made for supervision as advised by the sedationist.
7. Written and verbal post-operative instructions appropriate for both the sedation and the dental treatment have been given to the patient and escort/carer.
8. Advice has been given regarding precautions in the post-sedation period. This must be related to the dental treatment and the use of any local analgesia, the type of sedation and their duration. The precautions should include not drinking alcohol, operating machinery, driving or making important decisions for a specified period of time.
9. Arrangements for post-operative analgesia have been made where appropriate.
10. Arrangements are in place for out-of-hours advice.

in life support. The role of each of member of the team must be clearly defined and the procedures to be followed known and rehearsed at regular intervals. There must be evidence of regular scenario-based team training in the management of potential complications associated with conscious sedation. The provider of dental care and the provider of the sedation service must be able to maintain life support for a patient until such time as the emergency services are able to attend.
Clinical governance and audit

Conscious sedation procedures must be the subject of robust and regular audit in which all members of the team take part. The focus must be an ongoing review of procedures and processes with analysis of outcomes and modifications made to procedures and techniques as necessary.

Records of the audit process and outcomes from them must be maintained and be available for inspection. Regular high quality audit is an essential component of a service and is considered to be a core requirement for those delivering conscious sedation for patients.

In addition, clinical governance, clinical effectiveness and regular audit form a central part of risk management. In NHS institutions there are computerised reporting systems where clinical incidents must be recorded. Independent practitioners should parallel these processes to investigate all adverse events. Sedation teams must maintain high quality full clinical records and a written or electronic clinical log. Each clinical team must maintain continuous and contemporaneous records of the number and types of sedation cases performed as well as the rate of any complications that may have arisen.

Safe Sedation Practice for Healthcare Procedures\(^\text{22}\) describes a number of critical incidents that should be reported and investigated locally. Midazolam over-sedation and failure to monitor oxygen saturation during sedation (other than during inhalation sedation with nitrous oxide/oxygen) are defined as ‘never events’ by the Department of Health in England.\(^\text{22}\) These must be reported centrally in England and Wales to the National Reporting and Learning System\(^\text{23}\) and, if applicable, to the body commissioning the care.

This report recommends the use of a national system for recording adverse clinical incidents by all dentists, doctors and healthcare professionals who provide or directly support sedation for the delivery of dental care. This should be used both in NHS services and in the independent sector. The Safe Anaesthesia Liaison Group (SALG)\(^\text{24}\) aims to highlight potential or existing patient safety issues that fall in the anaesthesia care pathway. Part of the remit of SALG is to encourage incident reporting for the purpose of learning, which is facilitated by the confidential nature of the reports.

It is recommended that the use of this well-established mechanism by all those engaged in the delivery of conscious sedation in dentistry is explored.
Education and training

This report defines the standards for education and training in conscious sedation in the UK, the details of which are provided in Section 5: Education and training and in Appendix 1. All members of the delivery and care team must have undertaken appropriate validated education and training and demonstrated an acceptable level of competence by means of a robust assessment process. Courses that are solely didactic and skills-based without supervised clinical practice, assessment and external quality assurance do not constitute sufficient training for unsupervised practice in those clinical techniques.

Both knowledge and clinical skills must be maintained. It is the responsibility of individual team members to ensure that relevant continuing professional development to maintain knowledge, skills and competence is undertaken at appropriate intervals.25

For revalidation in a sedation technique, a practitioner must undergo a minimum of 12 hours of continuing professional development every 5 years that are relevant to the techniques practised. This applies to dentists, medical practitioners, recovery nurses, dental care professionals and all members of the team providing conscious sedation. Practitioners not regularly practising a technique must consider either the need for mentoring and/or retraining or discontinuing its use. (FAQ 10).

Educational courses intended to provide training in clinical delivery of conscious sedation and to prepare the team for independent practice must be assessed, be externally quality assured and incorporate supervised clinical practice. The IACSD through the dental faculties of the UK surgical royal colleges will accredit all courses in conscious sedation for dentistry other than those run by UK universities, Health Education England, NHS Education for Scotland, the Wales Deanery, the Northern Ireland Medical and Dental Training Agency, and Schools of Anaesthesia where quality assurance mechanisms including supervised clinical practice are in place. The Certificate in Dental Sedation Nursing of the National Examining Board for Dental Nurses (or any equivalent qualification from other accredited awarding bodies) is the recognised pathway for dental nurses wishing to train in the care of patients being treated under conscious sedation.26

Furthermore, through the dental faculties of the UK surgical royal colleges, the IACSD will form a sub-committee to accredit other providers of clinical courses for conscious sedation in dentistry. The membership of this sub-committee will contain appropriate experience and clinical expertise in dental sedation techniques as well as the assessment and quality assurance of education and training. Accreditation for a course can be retained for three years assuming there are no substantive changes to the programme. Appendix 2 sets out the requirements for course accreditation. (FAQ 4, 12, 14).

The content to be covered in the education and training of the dental team is described in the syllabuses in Appendix 1. These are derived from current documents produced by specialist societies,27–29 expert groups,26,29–32 and royal colleges.33 There is a further separate syllabus for
anaesthetists published by the Royal College of Anaesthetists. The syllabuses are preceded by a table of generic learning outcomes for training in conscious sedation in dentistry. Each of the five syllabuses is a standalone element.

**Syllabus 1:** Dentists: Basic conscious sedation techniques for children, young people and adults

**Syllabus 2:** Dentists: Advanced conscious sedation for young people and adults

**Syllabus 3:** Dentists: Advanced conscious sedation for children

**Syllabus 4:** Dental hygienists and therapists: Inhalation sedation

**Syllabus 5:** Dental nurses: Assisting during conscious sedation

The generic learning outcomes and the five syllabuses are contained in Appendix 1.
Sections

The further details of the report are provided in five sections:

1. Care pathways
2. Sedation techniques
3. Peri-operative care
4. Patient information
5. Education and training

Section 1: Care pathways

Primary dental care provides the majority of NHS dentistry across the UK, with community/salaried and hospital dental services providing additional care when required because of patient need and complexity. The data on sedation delivered to support care in hospitals are combined with those for general anaesthesia and information on the level of sedation services is not obtainable separately. Sedation services are also available in conjunction with private dental care and these data are not accessible. A report in Northern Ireland, however, suggests that just over half of sedation services are provided in the private sector.

The data from England indicate that there is currently a static overall volume of sedation services provided each year in primary dental care under the present system of commissioned NHS care. In 2013–2014, there were circa 136,000 courses of treatment involving the use of conscious sedation.

In-depth analysis reveals that there is marked variation, suggesting inequalities in access to NHS sedation services. There is variation in the rate of provision by region, age and socio-economic status. There is evidence of children and adults from all age groups having sedation as an adjunct to care with the peak age-band being children aged 6–12 years. Across almost all age groups, children and adults from more deprived areas make greater use of NHS sedation services. This indicates a clear social gradient that mirrors poor oral health and less frequent uptake of dental care. In Wales, the majority of sedation services are provided by the community dental service, with adults making up the majority of patients, which reflects the role of the community dental service in providing special care dentistry.

Research suggests that the need for sedation services may be higher than the level of current provision and that while most patients receiving sedation services do require this support, a minority may not. Patients should receive the appropriate support for care at the right time and in the right place. This report highlights the importance of having access to a range of supportive approaches to enable good ‘behaviour management’ through access to ‘behavioural therapies’ such as cognitive behavioural therapy as well as conscious sedation and general anaesthesia services. The provision of dental care in the NHS in the UK is moving towards the establishment of appropriate care pathways. The definition of care pathways describes a methodology for the mutual decision-making and organisation of care for a well-defined group of patients during a well-defined period.

A ‘whole systems approach’ should be taken to examine the level of need nationally (and locally) across service providers, with a care pathway approach being used to ensure that dental professionals have access to the necessary support services for their patients across healthcare organisations. This will ensure that patients receive
appropriate care at each stage of their dental journey. In support of this, planners and commissioners of services should audit the provision of these adjuncts to care, by assessing access, quality and capacity to meet need. The systems approach would examine the need of the people in the system and prioritise provision of services for those in greatest need. Information on local access to the full range of adjuncts should be clearly available for patients and dental care providers, with the needs of the patients being paramount in a patient-centred healthcare system.\footnote{43}

By way of an example, a generic care pathway for child patients is shown in Figure 2. This provides guidance on the most appropriate management of anxiety to facilitate optimal dental care and to determine the environment in which such care should be delivered. In respect of the dental care of children, additional clinical guidance for dentists is available.\footnote{44–49}

The use of this type of guidance provided by expert clinical groups is to be encouraged. It is anticipated that care pathways will become increasingly common in dentistry and that they will facilitate the commissioning of government-funded dental services, including those for conscious sedation in the provision of dental care.

---

**Figure 2**

A care pathway for children and young people aged 0–16 years

CDS = community dental services (formerly: salaried dental services) – in Scotland: public dental service;

IS = inhalation sedation; IV = intravenous; LA = local analgesia
The techniques available for conscious sedation in dentistry are tabulated below. The contents should be read in conjunction with the notes that follow the table. Table 1 specifies:

- the level of education and training required of the practitioner and quantifies the supervised clinical practice required to demonstrate competence
- the necessary life support skills for all team members
- the minimal monitoring requirements
- the nature of the clinical team required to deliver each modality
- the setting where the modality may be provided

Further details of the skills and knowledge required by the operator-sedationist and/or the sedationist and the other members of the team may be found in Appendix 1.
### Requirements for clinical sedation techniques. (FAQs 4, 16, 23, 24)

Notes:

i) Age
Patients who have not reached puberty are physiologically immature and will require a sedation team member having paediatric resuscitation skills. Providers and commissioners will need to consider this when planning services for this group of patients.

Any child under 12 years of age with complex oral needs or any child under 12 years who cannot be managed with either:

a) behavioural management techniques/local analgesia

or

b) local analgesia plus inhalation sedation

with the responsible dental practitioner having received appropriate training should be referred to a team having skills equivalent to those expected of a specialist/consultant in paediatric dentistry and a consultant in anaesthesia competent in sedation for dentistry for assessment and treatment in a facility equivalent to an NHS Acute Trust in England. This would include care provided by a managed clinical network or a recognised care pathway.

Any young person aged 12–16 years with complex oral needs or any young person aged 12–16 years who cannot be managed with either:

a) behavioural management techniques/local analgesia

or

b) local analgesia plus inhalation sedation

or

c) local analgesia plus midazolam (all routes)

with the responsible dental practitioner having received appropriate training should be referred to a team having skills equivalent to those expected of a specialist/consultant in paediatric dentistry and a consultant in anaesthesia competent in sedation for dentistry for assessment and treatment in a facility equivalent to an NHS Acute Trust in England. This would include care provided by a managed clinical network or a recognised care pathway. (FAQ 18, 20, 21).

ii) Terminology
Over the last decade, the terms ‘standard’/‘alternative’ and ‘basic’/‘advanced’ have been used to differentiate the most commonly employed sedation techniques from those used to manage the small number of patients for whom the simpler techniques do not provide appropriate anxiolysis. For adults, the first five techniques in Table 1 are ‘standard’ or ‘basic’ (but note that competency in intravenous sedation is mandatory for oral and intranasal sedation). For children under 12 years of age, only nitrous oxide/oxygen is considered to be ‘basic’. The ‘basic’ techniques all have an excellent safety record and are of proven efficacy for a wide range of patients.

The vast majority of patients (probably >95%) may be managed using one of these simple and cost-effective techniques, which are suitable for use by an appropriately trained and experienced operator-sedationist. However, it is essential that both training and experience are relevant to the age group being managed. It should also be borne

*Scotland: an NHS Board; Wales: a Health Board; Northern Ireland: a Health and Social Care Trust*
in mind that what are normally considered to be operator-sedationist techniques may sometimes be more effective and/or safer when the sedation is provided by a dedicated sedationist and a separate operator, for example when:

- the patient is medically compromised, has a physical disability or is emotionally challenging
- either the operator or the sedationist is relatively inexperienced
- the patient has a history of being particularly difficult to manage
- the dental procedure is complex or prolonged
- patients are at the extremes of age

**iii) Opioid + midazolam**
The use of a small single dose of an opioid (most commonly fentanyl) followed by titrated midazolam (intravenous) is considered suitable for the operator-sedationist working in a primary care setting on condition that the dentist and second appropriate person have successfully completed recognised training programmes, have an appropriate level of experience, and that only American Society of Anesthesiologists (ASA) grade I and II adults (>16 years of age) are treated.

**iv) Ketamine**
Ketamine is increasingly being used for paediatric conscious sedation in the UK, either alone or in combination with midazolam. Evidence that paediatric patients may be better managed using ketamine alone is accumulating but until this is published, it is impossible to offer detailed guidance. It should therefore currently only be used by an appropriately trained and experienced dedicated sedationist who is not also carrying out the dental treatment. This applies to all age groups.

**v) Patient-controlled sedation**
The IACSD is unaware of anyone currently providing patient-controlled sedation for paediatric dental sedation. The availability of licensed delivery systems and further dentistry-specific research might clarify the safety and efficacy of this technique.

**vi) Management of complications**
The term ‘rescue’ derives from anaesthetic practice and means the ability to respond appropriately to correct the adverse physiological consequences that can sometimes accompany inadvertent over-sedation (i.e. hypoventilation, loss of airway and hypoxia), for example if the patient unintentionally becomes deeply sedated, overshooting the intended target state of conscious sedation. As applied to conscious sedation for dentistry, it is taken to mean that a dentist using conscious sedation must be able to manage deep sedation and its attendant risks.

Anyone providing conscious sedation must be able to manage any event that might reasonably arise. The changing requirements from the GDC and the Resuscitation Council (UK) are reflected in this report. All the IACSD syllabuses (Appendix 1) state that practitioners must be able to perform Immediate Life Support/Paediatric Immediate Life Support, depending on the patient’s age, and that they must be able to recognise and manage sedation-related complications (including over-sedation, respiratory depression/apnoea, unconscious patient, airway obstruction, vomiting, idiosyncratic responses, delayed recovery, failure of conscious sedation). ‘Deployable’ airway competencies (including basic airway manoeuvres, the use of airway adjuncts and the ability to administer positive pressure ventilation) are mandatory. The widespread establishment of high-fidelity clinical skill and resuscitation teaching centres has facilitated the acquisition of these mandatory skills. (FAQ 16, 17).

**vii) Capnography**
Sampled exhaled gas or transcutaneous capnography may be appropriate for some ‘at risk’ ASA grade III/IV dental patients, particularly those receiving supplemental oxygen during sedation. However, despite the growing pressure for it to be used universally in the UK, until the results of dentistry-specific research are available, its routine use for ASA grade I and II dental patients lacks high level scientific validation and cannot be recommended. (FAQ 25).
viii) Dental nurse training
Dental sedation nurses (referred to historically as ‘the second appropriate person’) must be trained and experienced in the sedation technique being used. The National Examining Board for Dental Nurses (NEBDN) offers a qualification in dental sedation nursing (the Certificate in Dental Sedation Nursing [CDSN]) but, at present, less than 10% of sedation nurses have gained this award. Employers should encourage all sedation nurses to work towards this or an equivalent qualification. The CDSN is based on the relevant IACSD education and training syllabus contained in this report. ‘CDSN +’ indicates that additional drug/technique-specific training is required in addition to the CDSN. (FAQ 12, 13, 14, 15).

ix) Environment
Irrespective of the clinical setting, where multiple drugs (e.g. fentanyl/midazolam) or anaesthetic drugs (propofol, sevoflurane) are used to provide conscious sedation, the sedation team must have immediate access to the equivalent range of skills and facilities to be found in an NHS Acute Trust* for the prompt recognition and immediate management of adverse events. The classification of the environment as ‘primary’ and ‘secondary’ in Table 1 is convenient but must be interpreted sensibly as the facilities available in some primary care settings exceed those of some hospitals.

*Scotland: an NHS Board; Wales: a Health Board; Northern Ireland: a Health and Social Care Trust
During conscious sedation the patient responds to verbal commands. Cognitive function and physical co-ordination may be impaired but airway reflexes, ventilatory and cardiovascular functions are little affected. The sedationist or other person who has capability within his or her scope of practice must monitor the patient throughout the procedure. As well as monitoring the depth of sedation and the patient’s comfort, there must be a written contemporaneous record of the clinical and electro-mechanical monitoring of physiological systems required for specific sedation techniques.

The recommendations in Table 2 apply to ASA grade I/II patients receiving conscious sedation for dental treatment. Clinical monitoring involves checking the level of consciousness/depth of sedation, airway patency, respiration (rate and depth), skin colour, capillary refill, pulse rate, rhythm and volume while non-invasive blood pressure (NIBP) monitoring also records heart rate. NIBP is not essential in children. Intra-operative measurements may be useful in longer cases. Pulse oximetry provides a visual display and audible indication of arterial oxygen saturation as well as heart rate and rhythm. Audible alarms must not be silenced. Additional monitoring (e.g. end-tidal or transcutaneous capnography, electrocardiography) may be appropriate for ASA grade III/IV patients, particularly those with chronic lung disease.
Table 2. Intra-operative care and monitoring. (FAQ 24).

Sections

Section 4: Patient information

The report has emphasised the importance of full and comprehensive information being provided for patients, parents and carers. Examples of information for patients, those with parental responsibility and carers are provided both in this section and in Appendix 3. It is intended that these will form helpful guidance for dentists in the drafting of locally developed patient information, which must be given to patients in both verbal and written form. The issuing of correct and comprehensive patient information forms one essential aspect of valid consent.

Clear information must be provided that prepares patients for dental treatment under sedation. This information should explain the procedure, the pharmacological process, and the benefits and risks associated with the selected form of sedation.

It should be imparted as part of a face-to-face explanation to the patient at the time of clinical pre-operative assessment and must then be supported by the provision of written information. Best practice in the process of consent dictates that this information should be provided prior to the day of the procedure. In addition, information must be provided for patient escorts. For paediatric dentistry, information for those with parental responsibility and carers is also required, together with age appropriate information for the child or older adolescent.

Examples for children, young people, adults, parents and those with parental responsibility are given in Appendix 3. All the examples have been reviewed by both clinicians and lay representatives. The examples meet the requirements of plain English and have been approved by the dental faculties of the surgical royal colleges and the Royal College of Anaesthetists. They can be reproduced in their entirety with this acknowledgement. The examples may also be amended to meet the specific requirements of the clinician, in which case their approval by the royal colleges is no longer valid.

In Wales, there must be compliance with the Welsh Language Act.

The following core information must be included in any locally developed patient information:

*What is conscious sedation?*

This information must:
- explain the need for a robust medical assessment to ascertain a full medical, dental and social history prior to treatment
- give advice on other options and alternatives
- explain the fact that consciousness is maintained, and the difference between the effect of sedation and general anaesthesia
- explain the consent process
- give clear guidance on fasting
- explain what to expect during the recovery period
- explain clearly the requirement for a competent escort at discharge home
- describe the risks and benefits of the proposed type of sedation
What is inhalation sedation?

This information should:
• describe the use and administration of nitrous oxide/oxygen through a nosepiece
• explain the likelihood of any particular effects this might have and the need for care on discharge
• describe clearly the associated risks and the consent process

For paediatric patients, under the age of 16 years, information should be provided for parents or those with parental responsibility.

What is intravenous sedation?

This information should:
• give the reasons for the use of intravenous sedation
• explain its method of administration
• describe the process and the specific drug(s) to be used
• describe clearly the associated risks and the consent process
• confirm the need for a patient escort

In addition to information for adults, information must also be provided for parents or those with parental responsibility.

For intravenous sedation with multiple agents, there must be (in addition to the previously stated information) a clear explanation of the rationale for the technique. Explicit information regarding heightened risk to enable valid consent must be included.

What is oral sedation?

The information should:
• explain the nature of oral sedation to include the unpredictability of effect
• clarify that the sedative drug is given under the direct supervision of the sedationist, and reinforce the distinction between oral sedation and pre-medication
• confirm the need for intravenous access during the procedure
• describe clearly the associated risks and the consent process
• confirm the need for a patient escort

In addition to information for adults, information must also be provided for parents or those with parental responsibility.

What is transmucosal sedation?

The information should:
• explain the administration of the drugs via a nasal spray
• explain the time to effect of the sedation and confirm the need for intravenous access during treatment
• describe clearly the risks and benefits as well as the consent process, with consideration being given to the specific requirements regarding consent and limited capacity
• confirm the need for a patient escort

The information provided to patients must reflect the clinical guidance in relation to risk, consent, fasting and age appropriate sedation as stated in this report. (FAQ 26).
The following generic learning outcomes and syllabuses have been produced as a guide for both those currently practising or planning to practise conscious sedation for dentistry as well as those who provide or plan to provide education and training in conscious sedation for dentistry. These apply not only to the dental team but also to medical practitioners wishing to provide conscious sedation for dental procedures. Anaesthetists will follow the syllabus of the Royal College of Anaesthetists. It is envisaged that practitioners will map their education and training to the generic learning outcomes, knowledge, skills and attitudes described in the relevant syllabus, and that course providers (both existing and prospective) will use the information for the development, evaluation and review of their curricula.

The generic learning outcomes provide a high level description of the knowledge, skills and attitudes applicable to all members of the multi-disciplinary team, and encapsulate the broader context in which conscious sedation is delivered in clinical dental practice. As such, these learning outcomes apply to all five syllabuses.

Each syllabus describes the detailed knowledge, skills and attitudes required of specific members of the multi-disciplinary team providing care for dental patients requiring conscious sedation and may relate to a particular area of practice. They contain the following sections:

1. General professional conduct
   1.1 Maintaining good clinical practice
   1.2 Relationships with patients, parents and carers
2. Sedation-related content

Courses should be provided by nationally recognised institutions and bodies, and teachers should be appropriately experienced dental sedationists in the techniques that are being taught. Courses designed to lead to independent clinical practice require accreditation, the requirements for which are described in Appendix 2.

Training providers must ensure that all trainees understand the importance of complying with contemporary guidance relating to the environment, facilities and equipment required for each sedation technique.

Different legal and regulatory frameworks in the devolved authorities may necessitate amendments to some sections of the syllabuses (e.g. consent).

The learning outcomes are specific to the particular drugs listed. The development in the future of new treatment modalities and the regular review of existing ones will necessitate revision of the existing syllabuses as well as provision of specific education and training courses.
It is not envisaged that one course will offer training in the use of all drugs/drug combinations.

Although written for dental professionals, the principles in this document apply to all who administer conscious sedation for dentistry. The syllabuses define the knowledge, skills, attitudes and behaviours required of dental and medical practitioners wishing to train in the administration of conscious sedation for dentistry. This includes those anaesthetists not in possession of a Certificate of Completion of Training and documented evidence of satisfactory completion of equivalent training in conscious sedation for dentistry under the auspices of a Royal College of Anaesthetists approved training programme.

Appendix 1 contains:
- the generic learning outcomes
- Syllabus 1: Dentists: Basic conscious sedation techniques for children, young people and adults
- Syllabus 2: Dentists: Advanced conscious sedation for young people and adults
- Syllabus 3: Dentists: Advanced conscious sedation for children
- Syllabus 4: Dental therapists and dental hygienists: Inhalation sedation
- Syllabus 5: Dental nurses: Assisting during conscious sedation
Appendix 1: 
Training in conscious sedation: 
Generic learning outcomes

The following table describes the generic learning outcomes that should apply to all members of the multi-professional team involved in providing care for dental patients requiring conscious sedation, commensurate with their scope and level of practice. (FAQ 4, 18, 20, 21).

Sedation drug selection

- the indications and contraindications for conscious sedation in young people and adults using:
  - benzodiazepines
  - propofol
  - opioids

- the selection of the most appropriate agents for each patient taking into account:
  - proposed dental treatment
  - age and body weight
  - degree of anxiety
  - medical history
  - physical examination
  - social history
  - healthcare environment
  - healthcare team sedation training and experience

- the principle of 'minimum intervention' (the use of the smallest amount of a single drug or the least number of drugs that is likely to produce clinically effective, safe conscious sedation)

Administration of sedation

- appropriate clinical and electrical monitoring techniques (SaO₂, NIBP, ECG, end-tidal CO₂, BIS)
- appropriate drug dosage(s)
- appropriate administration techniques (in the correct order) of advanced sedation drugs
- how to recognise the conscious sedation endpoint
- the safe administration of propofol by one or more of the following techniques:
  - manual titration
  - patient-controlled infusion
  - target-controlled infusion
  - the operation of infusion devices
- indications, advantages and disadvantages of administering intra- and post-operative supplemental oxygen using nasal cannulas
- the effectiveness of conscious sedation

- recognise the indications and contraindications for conscious sedation in young people and adults using:
  - benzodiazepines
  - propofol
  - opioids

- select the most appropriate agents for each patient taking into account:
  - proposed dental treatment
  - age and body weight
  - degree of anxiety
  - medical history
  - physical examination
  - social history
  - healthcare environment
  - healthcare team sedation training and experience

- administer sedation according to the principle of 'minimum intervention' (the use of the smallest amount of a single drug or the least number of drugs that is likely to produce clinically effective, safe conscious sedation)

- take account of the indications and contraindications for conscious sedation in young people and adults as well as the various agents and routes of administration when planning individual patient care

- show continuous regard for patient safety
- demonstrate recognition of the conscious sedation endpoint and avoid going beyond it
- demonstrate the safe administration of propofol by one or more of the following techniques:
  - manual titration
  - patient-controlled infusion
  - target-controlled infusion
  - operate infusion devices

- administer intra- and post-operative supplemental oxygen
- assess the effectiveness of conscious sedation

FA  
PDP  
WBA
the process of selecting a safe, effective and appropriate sedation technique for the child in terms of both the drug selection and the route of administration

the indications and contraindications for conscious sedation drugs in children, including:
- nitrous oxide/oxygen
- benzodiazepines
- propofol
- opioids
- ketamine
- sevoflurane

recognise the indications and contraindications for conscious sedation drugs in children, including:
- nitrous oxide/oxygen
- benzodiazepines
- propofol
- opioids
- ketamine
- sevoflurane

the selection of the most appropriate agents for each child patient taking into account:
- proposed dental treatment
- age and body weight
- degree of anxiety
- medical history
- physical examination
- social history
- healthcare environment
- healthcare team sedation training and experience

administer sedation according to the principle of ‘minimum intervention’ (the use of the smallest amount of a single drug or the least number of drugs that is likely to produce clinically effective, safe conscious sedation)

take account of the indications and contraindications for conscious sedation in children as well as the various agents and routes of administration when planning individual patient care

choose a safe, effective and appropriate sedation technique for the child in terms of both the drug selection and the route of administration

recognise the indications and contraindications for conscious sedation in children using different routes of administration, including:
- inhalation
- intravenous
- oral
- transmucosal
- intramuscular

select the most appropriate agents for each patient taking into account:
- proposed dental treatment
- age and body weight
- degree of anxiety
- medical history
- physical examination
- social history
- healthcare environment
- healthcare team sedation training and experience

the principle of ‘minimum intervention’ (the use of the smallest amount of a single drug or the least number of drugs that is likely to produce clinically effective, safe conscious sedation)

**Good practice / medico-legal requirements**

- the medico-legal requirements relating to administering inhalation sedation
- act in accordance with the medico-legal requirements relating to administering inhalation sedation
- the operator’s legal requirements when there is a separate operator and sedationist
- act in accordance with the operator’s legal requirements when there is a separate operator and sedationist
- the training and responsibilities of the person (usually an appropriately trained and experienced dental nurse) who assists an operator-sedationist
- act in accordance with the requirements relating to the person (usually an appropriately trained and experienced dental nurse) who assists an operator-sedationist
- the situations in which a separate operator and sedationist are appropriate
- recognise the situations in which a separate operator and sedationist are required, and act accordingly
- the knowledge and experience another practitioner must have to be able to provide safe conscious sedation for a dentist without training in conscious sedation
- when it is safe to discharge a patient and when other actions might be required
- recognise when it is safe to discharge a patient and when other actions might be required
- post-operative and aftercare instructions appropriate to each individual, taking into account their social circumstances
- provide patients with appropriate discharge and post-operative instructions in a format that they can understand
- the recognition and management of sedation-related complications, including:
  - over-sedation
  - respiratory depression
  - unconscious patient
  - airway obstruction
  - vomiting
  - anaphylaxis
  - delayed recovery
  - failure of conscious sedation
- recognise and manage sedation-related complications, including:
  - over-sedation
  - respiratory depression
  - unconscious patient
  - airway obstruction
  - vomiting
  - anaphylaxis
  - delayed recovery
  - failure of conscious sedation
- current guidelines on:
  - gaining valid consent
  - teamwork
  - clinical holding/restraint
  - ending holding/restraint if required
  - appropriate record keeping
  - controlled drugs
- apply current guidelines on:
  - gaining valid consent
  - teamwork
  - clinical holding/restraint
  - ending holding/restraint if required
  - appropriate record keeping
  - controlled drugs
- consult and collaborate with colleagues in other specialties where necessary
- recognise the role of the operator and other members of the dental sedation team in the management of patients
- show regard for individual patient, family and/or carer needs
- recognise the importance of team training in the management of sedation/medical emergencies in the dental surgery
- show regard for individual patient needs when utilising guidelines

Assisting with the administration of sedation

- The preparation of the patient prior to the administration of conscious sedation
- The preparation of the treatment area prior to the administration of conscious sedation
- The physical signs of both conscious (moderate) and deep sedation as well as how to recognise the conscious sedation endpoint
- The equipment required for administration of intravenous, inhalational, oral and intranasal sedation
- The selection of a peripheral vein for cannulation, the signs and symptoms of extravascular injection, and the safe removal and disposal of an intravenous cannula
- How to check an inhalation sedation machine and scavenging system
- How to connect a breathing system, select an appropriate nasal mask, and adjust the gas flow rate and mixture on an inhalation sedation machine
- How to clinically monitor a patient to determine the level of consciousness, cooperation, respiration, heart rate and skin colour, and how to respond appropriately to changes
- The use of appropriate electrical monitoring techniques (SpO₂, NIBP, ECG, end-tidal CO₂, BIS) and how to respond to changes
- Common electrical monitoring artefacts and malfunctions
- Appropriate drug dosage(s)
- Appropriate drug administration techniques
- How to recognise the conscious sedation endpoint

 Conscious sedation techniques, including:
- Inhalation
- Intravenous
- Oral
- Transmucosal (intranasal, buccal)

Indications, advantages and disadvantages of administering intra- and post-operative supplemental oxygen using nasal cannula

The effectiveness of conscious sedation

The approved procedure for clearing and disinfecting the treatment area between patients, including the safe disposal of sedation equipment and unused drugs

Demonstrate the patient checks required prior to the administration of conscious sedation

Demonstrate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Dedicate the patient checks required prior to the administration of conscious sedation

Dedicate the preparation of the notes, equipment and treatment area required prior to the administration of conscious sedation

Select the equipment required for administration of intravenous, inhalational, oral and intranasal sedation

Prepare and assist in the safe delivery of sedation drugs

Show a caring attitude to the safety of the patient and understand the importance of preparation prior to the administration of conscious sedation

Show continuous regard for patient safety
Good practice / medico-legal requirements

- the medico-legal requirements relating to administering sedation drugs
- the legal requirements of the members of the dental team both when there is an operator-sedationist or a separate operator and sedationist
- the training and responsibilities of the person (usually an appropriately trained and experienced dental nurse) who assists an operator-sedationist
- the situations in which a separate operator and sedationist are appropriate
- when it is safe to discharge a patient and when other actions might be required
- post-operative and aftercare instructions appropriate to each individual, taking into account their social circumstances
- the recognition and management of sedation-related complications, including:
  - over-sedation
  - respiratory depression
  - unconscious patient
  - airway obstruction
  - vomiting
  - anaphylaxis
  - delayed recovery
  - failure of conscious sedation
- current guidelines on:
  - gaining valid consent
  - teamwork
  - clinical holding/restraint
  - ending holding/restraint if required
  - appropriate record keeping
  - controlled drugs
  - ‘off-licence’ use of drugs

- act in accordance with the medico-legal requirements relating to administering sedation drugs
- act in accordance with the legal requirements for dental nurses and recognise those for other members of the team
- act in accordance with the requirements relating to the person (usually an appropriately trained and experienced dental nurse) who assists an operator-sedationist
- recognise the situations in which a separate operator and sedationist are required, and act accordingly
- recognise when it is safe to discharge a patient and when other actions might be required
- provide patients with appropriate discharge and post-operative instructions in a format that they can understand
- recognise and manage sedation-related complications, including:
  - over-sedation
  - respiratory depression
  - unconscious patient
  - airway obstruction
  - vomiting
  - anaphylaxis
  - delayed recovery
  - failure of conscious sedation
- apply current guidelines on:
  - gaining valid consent
  - teamwork
  - clinical holding/restraint
  - ending holding/restraint if required
  - appropriate record keeping
  - controlled drugs
  - ‘off-licence’ use of drugs

- recognise the role of all the members of the dental sedation team in the management of patients
- show regard for individual patient, family and/or carer needs
- recognise the importance of regular team training in the management of sedation/medical emergencies
- show regard for individual patient needs when utilising guidelines

**Key:**
- **Teaching and learning methods**
  - ACI = audit/critical incident analysis
  - CA = clinical attachment
  - CBL = case-based learning
  - SDL = self-directed learning
  - ST = structured teaching

- **Assessment methods**
  - FA = formal assessment
  - MSF = multi-source feedback
  - PDP = personal development portfolio
  - WBA = workplace-based assessment
Appendix 2: Course accreditation

1. Applications for accreditation of courses leading to independent practice must include the submission of a curriculum that complies with the checklist below:
   - Purpose of the course
   - Aims and objectives of the course
   - Learning outcomes mapped against the syllabus: knowledge, skills, attitudes and behaviours
   - Course content mapped against the syllabus: knowledge, skills, attitudes and behaviours
   - Proposed course programme
   - Course providers: qualifications and relevant experience
   - Methods of learning, assessment and evaluation
   - Details of supervised clinical practice
   - Selection criteria for candidates
   - Venue for course and/or clinical skills training (outlining suitability)
   - Submission of a draft course certificate to record trainee attendance, continuing professional development hours – This must incorporate an explicit statement itemising the knowledge and/or skills and/or competencies gained by the trainee on successful completion. The certificate must include the names and GDC numbers of the trainee and course provider(s).
   - Internal and external quality control and assurance processes

2. Accreditation for a course may be retained for three years provided that there have been no substantive changes to the course/training programme.

3. Records of training and assessment for every course should be retained by trainees as part of their log of continuing experience. The lead course provider should also retain all the records of training as well as the course evaluations and attendance sheets. Records of training should be retained by the course provider for a minimum of five years.

4. In addition, a summary of the course evaluation should be submitted to the IACSD, which will reserve the right to inspect all the records relating to a course.

5. With revalidation in prospect, all trainers should be working towards collecting and maintaining documented evidence of clinical practice (e.g. log records). Trainers should conform to equality and diversity legislation.

6. Supervised clinical practice should contain workplace-based assessments (WBAs) and patient feedback questionnaires. The WBAs should sample the organisational aspects of conscious sedation and the whole patient experience from assessment to discharge. They should cover a wide a range of patient care. One WBA should assess the management and provision of an entire patient episode of care. This evaluation must be made by an external assessor competent in the relevant sedation technique.

7. For revalidation in a sedation technique, the practitioner should undergo a minimum of 12 hours of verifiable continuing professional development every five years in the technique(s) being practised. However, practitioners not regularly practising a technique must consider the need for mentoring and/or retraining. (FAQ 4, 5, 7, 8, 9, 10).
Transitional arrangements

From the time of publication of this report (first edition 2015), no healthcare professional should commence the provision of conscious sedation for dental patients without the training described in this report having been satisfactorily completed. However, it is appreciated that there are experienced practitioners currently providing conscious sedation for dentistry who have not received the formal postgraduate training as described in this report. In order to maintain a service for patients, it is appropriate to have ‘grandfathering’ arrangements in place so that such practitioners can continue to provide conscious sedation services, assuming that they comply with the guidance laid down in this document.

There is also an understanding that it is appropriate to ensure a robust process of continuing education and monitoring of all healthcare practitioners providing sedation for dentistry, not all of whom will have benefitted from the initial competency-based training described in this document. For clinicians initially trained prior to the publication of this report, the following transitional arrangements are recommended:

1. Sedation practitioners should maintain a log in either written or electronic form of all sedation cases undertaken, with comprehensive details of patient type, baseline vital signs, sedation agent used/route/dose/reversals/untoward incidents etc.

2. Sedation practitioners and their clinical teams must undertake the similar, validated continuing professional development required for those following the pathway of training recommended in this report.

3. Sedation practitioners must undertake sedation-based audit and reflection frequently and regularly in each location sedation is provided.

4. Sedation practitioners and their clinical teams must be competent in the appropriate ‘rescue’ skills described in this report for the techniques of conscious sedation that are practised.

5. Sedation practitioners must meet the requirements for the environment and equipment and the patient pathway checklist described in Section 1: Care pathways.

6. Sedation practitioners in primary care should ensure that appropriate clinical governance is in place to comply with the standards set in this report.

The records for points 1–6 above should be available to those who commission or carry responsibility for NHS provision of conscious sedation for dentistry. These requirements also apply to those practising conscious sedation for dentistry outwith the NHS. (FAQ 3, 6, 10, 12, 22).
Appendix 3: Examples of patient information

This appendix contains examples of patient information to be used for patients, those with parental responsibility and carers. Their use is subject to the conditions described in Section 4: Patient information. (FAQ 26).

Contents

Example 1: What is conscious sedation? (An introduction for adult patients) .................. 90

Sedation-specific information for adults
Example 2: Inhalation sedation .................. 91
Example 3: Intravenous sedation .................. 92
Example 4: Intravenous sedation with more than one drug .................. 94
Example 5: Oral sedation .................. 96
Example 6: Transmucosal sedation: Information for parents and carers .................. 98
Example 7: Transmucosal sedation: Pictorial sequence .................. 100
Example 8: The day of your dental procedure .................. 101
Example 9: Patient escort information .................. 102

Sedation-specific information for parents, those with parental responsibility, children and young people
Example 10: Inhalation sedation: Parents or those with parental responsibility for children and young people aged under 16 years .................. 107
Example 12: Intravenous sedation: Parents or those with parental responsibility for children and young people aged under 16 years .................. 109
Example 13: Intravenous sedation: Young people aged 12–16 years .................. 109
Example 14: Oral sedation: Parents or those with parental responsibility for children and young people aged under 16 years .................. 111
Example 15: Dental filling: Pictorial sequence for young children .................. 113
Example 1:
What is conscious sedation?
(An introduction for adult patients, to be used in conjunction with sedation-specific information)

Your dentist has recommended that you have your dental treatment with the help of sedation. Sedation is when drugs are used to make you feel less anxious and more relaxed. It will make you drowsy, less aware of what is happening and with few memories of what has happened to you during your treatment. It does not make you unconscious and you will be aware of what is happening.

Once you are sedated, the dentist may use local anaesthetic around the site of the dental treatment. Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections you need will then be given through this numbed area to minimise any discomfort.

Sedative drugs (medicines) can be given in a number of ways. Your dentist will decide, with you, which type is the best for your planned dental treatment.

There are different levels of sedation and several methods can be used. You may have sedation:

- by breathing in gas through a nosepiece (inhalation)
- by injection into a vein in your hand or arm (intravenous)
- by swallowing a medicine (oral)
- by placing a medicine under your tongue or into the nose (transmucosal)

Your dentist will discuss the best method to use for you and your treatment. The dentist will give you some information about the type of sedation you will be having for your treatment.

The dentist who agrees with you the plan for your treatment with sedation will give you some instructions to follow. These are important for your safe and comfortable care. For most types of sedation, you will need someone to come with you on the day of your treatment so that he or she can look after you when you go home. The dentist will confirm with you if you will need someone to act as an escort in this way. Your escort will also be given some important information about how best to look after you following your treatment under sedation.

This information is a general guide for patients having dental treatment with sedation. As part of the face-to-face discussions with your dentist, you may be given advice that is specific to your treatment plan. This may differ in some areas to the general principles outlined here.

Before any treatment is started, the dentist will ask you to confirm your consent. This means that you understand the planned treatment and how you will receive the sedation.

If you have any questions or are unclear about having your sedation, then do not hesitate to ask your dentist.
Example 2:
Inhalation sedation

Inhalation sedation means that the sedation is given as a gas. Anxiety is reduced by breathing nitrous oxide with oxygen, given as a mixed gas. The dentist will give you the gas through a nosepiece. This will not cover your mouth.

What to expect

It is usual to have two appointments. The first appointment will be for an assessment when your dental treatment under sedation will be planned and discussed with you. The dental treatment under sedation will take place at the second and subsequent appointments. If the treatment is needed as an emergency, it may be possible to have some treatment under sedation at the first appointment.

It is important that you let the dentist know your medical history and any medicines that you are taking.

If you think you may be pregnant, you need to let the dentist know. You may need to come back to have your treatment at another time. You should let your dentist know if you are breastfeeding.

The dentist will confirm whether you need to restrict what you eat or drink on the day of treatment. If you have any questions or are unclear about having your sedation, then do not hesitate to ask your dentist.

As you receive the gas via a nosepiece, you may get a feeling of warmth throughout your body as well as some mild tingling and light-headedness. You will stay awake and in control of all your reflexes, such as coughing.

Once you are sedated with the gas, the dentist may use local analgesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injection that you may need can then be given through this numbed area to reduce the chance of any discomfort.

After the treatment

You are unlikely to have any side effects, such as feeling sick or headache. At the end of the procedure, the dentist will give you some extra oxygen to make you feel more alert. This will speed up your recovery from the effects of the sedation.

You will spend time in the recovery area after the treatment is over. You will be checked by the dentist or an appropriate member of the dental team before you go home. It is not always necessary to have someone with you following this type of simple inhalation sedation. You may be advised not to drive a car, ride a bicycle or operate machinery for up to 2 hours following your treatment.

You will be given information relating to any local analgesia and the dental treatment you have received. The dental team will also advise you about any medicines you may need while recovering from the treatment. You will be given a telephone number of who to contact if you have any problems as a result of the treatment.
Example 3: Intravenous sedation

Your dentist has recommended that you have intravenous sedation. This means that a sedative drug (medicine) is given to you by injection into a vein. The sedation makes you drowsy and helps reduce anxiety.

Intravenous sedation is usually given by using a single drug called midazolam. A dose of the drug is chosen for you individually. It is given by injection. This is usually into a vein in the back of your hand or in your arm through a cannula.

A cannula is a thin flexible tube. A needle is used to put the cannula in but is then removed immediately. It is normal to feel a sharp scratch when the cannula is inserted. A local anaesthetic paste or liquid can be used first to reduce the pain of the injection. Once the cannula is in the vein, the sedation drug can be given without using any more needles. The cannula remains in until the dentist has checked that you have recovered from the sedation but it will be removed before you go home.

It is usual to have at least two appointments. The first appointment will be an assessment when your dental treatment under sedation will be planned and discussed with you. The dental treatment under sedation will take place at the second and subsequent appointments. If the treatment is needed as an emergency, it may be possible to have some treatment under sedation at the first appointment.

Your dentist and members of the dental team are trained to give sedation. They watch you closely and treat any problems that may develop. They are also required to use appropriate monitoring equipment during sedation. There will be a recovery area where you will be observed until you have made a full recovery from the sedation.

As with the administration of any medicines, there are risks associated with intravenous sedation. These might include:

- A reduction of oxygen in the blood stream due to poor breathing during sedation. You may be asked by your dentist/sedationist to take deep breaths to correct this. Your breathing and oxygen levels will be monitored throughout the procedure.
- Bruising at the site of the cannula. This may take several days to fade completely.

Very rare risks include allergic reactions to the sedative drugs that you have been given or vomiting during the procedure. Your dentist/sedationist will discuss any concerns that you may have prior to the procedure taking place. It is important that you let the dentist know your medical history, including any medicines that you are taking. The dentist will need to know if you have ever had any problems with having either sedation or a general anaesthetic.

If you think you may be pregnant, you need to let the dentist know. You may need to come back to have your treatment at another time. You should let the dentist know if you are breastfeeding.

Your dentist will discuss with you and explain what you are able to eat and drink prior to your appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

The information provided here is a general guide for patients having dental treatment with sedation. As part of the face-to-face discussions with your dentist, you may be given advice that is specific to your treatment plan. This may differ in some areas to the general principles outlined here.

Before any treatment is started, the dentist will ask you to confirm
consent. This means that you understand the planned treatment and how you will receive the sedation.

**What to expect**

You will remain conscious during this kind of sedation.

You may experience a temporary loss of memory during the time that you are sedated. Many patients have no memory of the procedure at all. You may feel unsteady on your feet for some hours after the procedure. Your ability to think clearly and make judgements may be affected for the next 24 hours. You may experience some forgetfulness.

Once you are sedated, the dentist can use local analgesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections that you may need can be given through this numbed area to reduce the chance of any discomfort.

You will spend some time in the recovery area following your treatment. You will be checked by the dentist or the person giving you the sedation before you can go home. You must be accompanied by an able-bodied adult who can take responsibility for you following your treatment. This person may need to stay with you overnight. If arrangements have not been made for someone to accompany you after treatment, you will not be able to have the sedation.

If you have any questions or are unclear about having your sedation, then do not hesitate to ask your dentist.

**After the treatment**

Your judgement will be affected by the drugs. This is similar to the effects of consuming alcohol. You should not drive a car, ride a bicycle or operate machinery until the following day. In some cases, this may be for as long as 24 hours. You should also not take responsibility for the care of others, use sharp implements or cook. It would be unwise to make any irreversible decisions for up to 24 hours following your treatment. Owing to the after effects of the drugs used, care should be taken when using the internet for personal communication.

Before you are discharged, the dentist or dental nurse will give you and the adult accompanying you (escort) important information about your care. You will be given information relating to any local analgesia and the treatment you have received. The dentist will also provide details of pain relief as well as how and when to take other prescription medicines.

You will be given a telephone number of who to contact if you have any problems as a result of your treatment.
More than one sedative medicine can be used for people having more complicated dental procedures or those with severe anxiety. Your dentist will tell you if this applies to you.

A dose of the sedative drugs will be chosen for you individually and given by injection. This is usually into a vein in the back of your hand or in your arm through a cannula.

A cannula is a thin flexible tube. A needle is used to put the cannula in but is then removed immediately. It is normal to feel a sharp scratch when the cannula is inserted. A local anaesthetic paste or liquid can be used first to reduce the pain of the injection. Once the cannula is in the vein, the sedation drugs can be given without using any more needles. The cannula remains in until the dentist has checked that you have recovered from the sedation but it will be removed before you go home.

It is usual to have at least two appointments. The first appointment will be an assessment when your dental treatment under sedation will be planned and discussed with you. The dental treatment under sedation will take place at the second and subsequent appointments. If the treatment is needed as an emergency, it may be possible to have some treatment under sedation at the first appointment.

Your dentist and members of the dental team are trained to give sedation. They watch you closely and treat any problems that may develop. They are also required to use appropriate monitoring equipment during sedation. There will be a recovery area where you will be observed until you have made a full recovery from the sedation.

As with the administration of any medicines, there are risks associated with intravenous sedation. Sedation with more than one drug can increase the risk of complications. Risks include:

- A reduction of oxygen in the blood stream due to poor breathing during sedation. You may be asked by your dentist/sedationist to take deep breaths to correct this. Your breathing and oxygen levels will be monitored throughout the procedure.
- Bruising at the site of the cannula. This may take several days to fade completely.

Very rare risks are allergic reactions to the sedative drugs that you have been given or vomiting during the procedure. There is a small risk of you becoming more deeply sedated than intended when having more than one sedative drug. Your dentist/sedationist will discuss any concerns that you may have prior to the procedure taking place.

It is important that you let the dentist know your medical history and any medicines that you are taking. The dentist will need to know if you have ever had any problems with having either sedation or a general anaesthetic.

If you think you may be pregnant, you should let the dentist know. You may need to come back to have your treatment at another time. You should let your dentist know if you are breastfeeding.

Your dentist will discuss with you and explain what you are able to eat and drink prior to your appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

The information provided here is a general guide for patients having dental treatment with sedation. As part of the face-to-face discussions with your dentist, you may be given advice that is specific to your treatment plan. This may

---

Example 4:

**Intravenous sedation with more than one drug**

More than one sedative medicine can be used for people having more complicated dental procedures or those with severe anxiety. Your dentist will tell you if this applies to you.

A dose of the sedative drugs will be chosen for you individually and given by injection. This is usually into a vein in the back of your hand or in your arm through a cannula.

A cannula is a thin flexible tube. A needle is used to put the cannula in but is then removed immediately. It is normal to feel a sharp scratch when the cannula is inserted. A local anaesthetic paste or liquid can be used first to reduce the pain of the injection. Once the cannula is in the vein, the sedation drugs can be given without using any more needles. The cannula remains in until the dentist has checked that you have recovered from the sedation but it will be removed before you go home.

It is usual to have at least two appointments. The first appointment will be an assessment when your dental treatment under sedation will be planned and discussed with you. The dental treatment under sedation will take place at the second and subsequent appointments. If the treatment is needed as an emergency, it may be possible to have some treatment under sedation at the first appointment.
differ in some areas to the general
principles outlined here.

Before any treatment is started,
the dentist will ask you to confirm
consent. This means that you
understand the planned treatment
and how you will receive the
sedation.

**What to expect**

You will remain conscious during
this kind of sedation.

You may experience a temporary
loss of memory during the time
that you are sedated. Many
patients have no memory of the
procedure at all. You may feel
unsteady on your feet for some
hours after the procedure. Your
ability to think clearly and make
judgements may be affected
for the next 24 hours. You may
experience some forgetfulness.

Once you are sedated, the dentist
can use local analgesia (pain relief
that numbs the site of the dental
treatment). Local anaesthetic
as a paste is sometimes used to
numb the site of the treatment.

Any injections that you may need
can be given through this numbed
area to reduce the chance of any
discomfort.

You will spend some time in the
recovery area following your
treatment. You will be checked by
the dentist or the person giving
you the sedation before you can
go home.

You **must** be accompanied by an
able-bodied adult who can take
responsibility for you following
your treatment. This person **must**
be able to stay with you overnight.
If arrangements have not been
made for someone to accompany
you after treatment, you will not be
able to have the sedation.

If you have any questions or
are unclear about having your
sedation, then do not hesitate to
ask the dentist.

**After the treatment**

Your judgement may be affected
by the drugs. This is similar to
the effects of consuming alcohol.
You should not drive a car, ride
a bicycle or operate machinery
until the following day. In some
cases, this may be for as long as
24 hours. You should also not
take responsibility for the care of
others, use sharp implements or
cook. It would be unwise to make
any irreversible decisions for 24
hours following your treatment.
Owing to the effects of the drugs
used, care should be taken when
using the internet for personal
communication.

Before you are discharged, the
dentist or dental nurse will give
you and the adult accompanying
you (escort) important information
about your care. You will be given
information relating to any local
analgesia and the treatment you
have received. The dentist will also
provide details of pain relief as well
as how and when to take other
prescription medicines.

You will be given a telephone
number of who to contact if you
have any problems as a result of
your treatment.
Oral sedation means that the sedation drugs are swallowed as a tablet or liquid. It takes about 10 minutes for the effects of the drug to work.

Once you are sedated, you will usually have a small cannula placed in the back of your hand or in your arm.

A cannula is a thin flexible tube. A needle is used to put the cannula in but is then removed immediately. It is normal to feel a sharp scratch when the cannula is inserted. A local anaesthetic paste or liquid can be used first to reduce the pain of the injection. Once the cannula is in the vein, the sedation drug can be given without using any more needles. The cannula remains in until the dentist has checked that you have recovered from the sedation but it will be removed before you go home.

It is usual to have at least two appointments. The first appointment will be an assessment when your dental treatment under sedation will be planned and discussed with you. The dental treatment under sedation will take place at the second and subsequent appointments. If the treatment is needed as an emergency, it may be possible to have some treatment under sedation at the first appointment.

Your dentist and members of the dental team are trained to give sedation. They watch you closely and treat any problems that may develop. They are also required to use appropriate monitoring equipment during sedation. There will be a recovery area where you will be observed until you have made a full recovery from the sedation.

As with the administration of any medicines, there are risks associated with oral sedation. Risks include:

- A reduction of oxygen in the blood stream due to poor breathing during sedation. You may be asked by your dentist/sedationist to take deep breaths to correct this. Your breathing and oxygen levels will be monitored throughout the procedure.
- Bruising at the site of the cannula. This may take several days to fade completely.

Very rare risks are allergic reactions to the sedative drugs that you have been given or vomiting during the procedure. Your dentist/sedationist will discuss any concerns that you may have prior to the procedure taking place.

It is important that you let the dentist know your medical history and any medicines that you are taking. The dentist will need to know if you have ever had any problems with having either sedation or a general anaesthetic.

If you think you may be pregnant, you should let the dentist know. You may need to come back to have your treatment at another time. You should let your dentist know if you are breastfeeding.

Your dentist will discuss with you and explain what you are able to eat and drink prior to your appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

The information provided here is a general guide for patients having dental treatment with sedation. As part of the face-to-face discussions with your dentist, you may be given advice that is specific to your treatment plan. This may differ in some areas to the general principles outlined here.

Before any treatment is started, the dentist will ask you to confirm consent. This means that you understand the planned treatment and how you will receive the sedation.
**What to expect**

You will remain conscious during this kind of sedation. You may experience a temporary loss of memory during the time that you are sedated. Many patients have no memory of the procedure at all. If arrangements have not been made for someone to accompany you after treatment, you will not be able to have the sedation.

If you have any questions or are unclear about having your sedation, then do not hesitate to ask your dentist.

**After the treatment**

Your judgement may be affected by the drugs. This is similar to the effects of consuming alcohol. You should not drive a car, ride a bicycle or operate machinery until the following day. In some cases, this may be for as long as 24 hours. You should also not take responsibility for the care of others, use sharp implements or cook. It would be unwise to make any irreversible decisions for 24 hours following your treatment.

Owing to the effects of the drugs used, care should be taken when using the internet for personal communication.

Before you are discharged, the dentist or dental nurse will give you and the adult accompanying you (escort) important information about your care. You will be given information relating to any local analgesia and treatment you have received. The dentist will also provide details of pain relief as well as how and when to take other prescription medicines.

You will be given a telephone number of who to contact if you have any problems as a result of your treatment.
What is transmucosal sedation?

The child or adult in your care may require dental treatment under sedation. Anxiety can be reduced by sedative drugs (medicines), which also make the patient drowsy. The dentist will be able to explain why the patient might benefit from having sedation.

Transmucosal sedation is generally given through a fine spray, which is squirted into the nose. The sedation drugs are absorbed through the lining of the nose and enter the bloodstream. It can take 5–10 minutes for the effects of the drug to work.

Once the sedation medicine has taken effect, for the patient’s safety, a needle is used to place a cannula (small plastic tube) in a vein in the back of the hand or in the arm. The dentist will use the cannula to reverse the effects of the sedation if necessary. A cream containing local anaesthetic may be used to make the injection site numb before the cannula is inserted.

Benefits and risks of transmucosal sedation

Transmucosal sedation reduces anxiety and fear of dental treatment. This is particularly helpful if the patient is having a long, uncomfortable or more complicated procedure.

The dentist and members of the dental team are trained to give sedation. They watch the patient closely and treat any problems that may develop. An oxygen supply will be available and oxygen will be given by mask if necessary. They are also required to use appropriate monitoring equipment during sedation. There will be a recovery area where the patient will be observed until he or she has made a full recovery from the sedation.

It is a widely used technique but, as with the administration of any medicines, there are risks associated with intranasal sedation. These risks include:

- A reduction of oxygen in the blood stream due to poor breathing during sedation. The patient may be asked by the dentist/sedationist to take deep breaths to correct this. The dentist/sedationist will continually monitor the patient’s breathing and oxygen levels throughout the procedure.
- Bruising at the site of the cannula. This may take several days to fade completely.

Very rare risks are allergic reactions to the sedative drugs the patient has been given or vomiting during the procedure. The dentist/sedationist will discuss any concerns that you may have about the patient prior to the procedure taking place.

What to expect

The method of dental treatment planned for the patient in your care will be discussed with you at a separate assessment appointment. The dental treatment will take place at second and subsequent appointments. In exceptional circumstances, treatment may be carried out on the same day as assessment. It is important that the dentist knows of any recent changes in the patient’s medical history and of any medicines being taken.

If you think the patient may be pregnant or breastfeeding, you need to let the dentist know. The patient may need to come back to have the treatment at another time.

Before the treatment is started, the dentist will need to take a full medical history and, if necessary, contact the patient’s general medical practitioner or specialist. The patient will need to have their blood pressure taken with a cuff on their arm and the level of oxygen in their blood measured with a clip on their finger.
How to prepare the patient

The information provided here is to help parents or carers understand the process of sedation. It is a general guide. As part of the face-to-face discussions with the dentist, the patient in your care may be given specific advice that may differ from the general principles outlined here.

There are complicated rules regarding consent for patients with limited capacity. The dentist will explain to you and the patient what steps need to be taken to ensure that consent is properly obtained. No treatment can be started without consent.

Additional information, with pictures, has been developed to be used with this information. The pictures help explain the procedures and effects of sedation. The treatment pictures appear at the end of this leaflet.

The dentist will discuss with you and explain what the patient is able to eat and drink prior to the appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

If the patient is unwell on the day with cold/flu symptoms or any contagious illness, please contact the dentist for advice. The appointment may need to be rearranged.

What will happen during the sedation?

The patient will remain conscious during the sedation but may experience some temporary loss of memory during the time that he or she is sedated. Many patients have no memory of the procedure at all. Patients may feel unsteady on their feet for some hours after the procedure. They may be affected for the rest of the day. They may experience some forgetfulness.

The patient will be monitored by the dentist and the dental team during the procedure. This will include measurements of blood pressure, heart rate and oxygen levels at regular intervals.

Once the patient is sedated, and feels drowsy and relaxed, the dentist can use local analgesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections that the patient may need can then be given through this numbed area to reduce the chance of any discomfort.

The patient will spend some time in the recovery area following the treatment. He or she will be checked by the dentist or the person giving the sedation and will not be allowed to go home until alert and responsive. The patient will need to be accompanied home by an able-bodied adult who can take responsibility for him or her for the rest of the day. Escorts should not bring other children with them on the day of the treatment.

Children may not return to school and should not participate in active sports for the rest of the day. You may wish to make plans about how best to travel home with the patient following treatment.

All patients need to be supervised by a responsible adult for the remainder of the day. The parent/carer may need to make arrangements for the care of other children or elderly dependent relatives during this time.

Adult patients should be aware that their judgement may be affected and care should be taken for the next 24 hours if the patient is using the internet for personal communication. They are advised not to drive, ride a bicycle or operate machinery until the following day or, in some cases, for 24 hours.

You will be given information relating to any local anaesthetic or treatment that the patient has received. The dental team will give you advice about any medicines the patient will need while recovering from the treatment. You will be given a telephone number of who to contact if you have any concerns.
Example 7: Transmucosal sedation: Pictorial sequence

The design and artwork of Dr Charlotte Curl are gratefully acknowledged.
Example 8:
The day of your dental procedure

Please arrive promptly for your appointment.

Do not bring children with you.

Make sure that you have followed any advice that you have been given by your dentist about eating and drinking before your appointment.

Bring with you a list of any medicines that you are currently taking. You should take your routine medicines on the day of the procedure. Please let the dentist know if your medical history has changed since you last saw the dentist.

If you think you may be pregnant, you need to let the dentist know. You may need to come back to have your treatment at another time. You should let the dentist know if you are breastfeeding.

It is sensible to wear loose, comfortable clothing and flat shoes. You may need to remove any contact lenses so remember to take your glasses or a replacement pair of lenses for use once the treatment is finished.

The dentist will need to monitor you carefully while you are sedated. To help with this, please remove nail varnish and do not wear excessive make up or jewellery.

Do not bring valuables with you.

If you feel unwell on the day of the procedure, please telephone the number provided.

If you have been asked to arrange for someone to go home with you, it is essential that this person is available. If you do not have an escort, you will not be able to have your procedure under sedation.

After your treatment, you will be given a telephone number of who to contact if there are any problems.
Example 9:

Patient escort information

Important information for adults accompanying patients having dental treatment with sedation

You have been asked to accompany someone who is having dental treatment under sedation.

Patients can feel less anxious if they receive a sedative drug (medicine) before or during their dental treatment. The drugs used can cause some patients to feel a little disorientated or confused for a short time after the treatment. It is important that someone will be responsible for them and take care of them for the remainder of the day. Occasionally, it may be necessary for someone to stay with them overnight.

It is important that you follow these instructions. The patient will have been given a telephone number of who to contact if you have any concerns.

The patient will not be allowed to go home until the dentist is satisfied that the patient is in the care of a responsible adult (over 18 years of age). The escort must be present with the patient as they leave the dental surgery. Some patients take a little longer than others to be ready to go home so please be aware that a precise time cannot always be given.

The patient’s judgement (ability to think clearly) is likely to be affected. Patients should not make any irreversible decisions for up to 24 hours following their treatment.

Patients should be encouraged to rest for a while once they are home. It is not recommended for them to be in charge of others until the next day. Care should be taken when cooking or using domestic appliances.

Patients should not drive a vehicle, ride a bicycle, operate machinery or drink alcohol until the following day and, in some cases, for up to 24 hours. The dentist will advise the patient on the day of treatment. Owing to the after effects of the drugs used, care should be taken when using the internet for personal communication.

The dentist will explain to the patient which pain relief medicines he or she may take. Patients should take their usual prescribed medicines unless directed otherwise by their doctor or dentist.
What is inhalation sedation?
The child in your care may require dental treatment under inhalation sedation. This will help the child feel less anxious, slightly drowsy and more relaxed for the dental treatment. Inhalation sedation does not make the child unconscious. The child remains awake but may feel warm and detached. The child’s memory of the treatment afterwards may be slightly reduced.

Inhalation sedation means that the child will breathe a mixture of nitrous oxide and oxygen from a nosepiece placed on the nose. This will have a relaxing effect.

Benefits and risks of inhalation sedation
Inhalation sedation is used to reduce anxiety and fear of dental treatment. This makes the child more co-operative. This is particularly helpful if the child is having a longer, uncomfortable or more complicated procedure. It is a widely used technique.

The dentist and members of the dental team are trained to give sedation. They watch the child closely and treat any problems that may develop. The nitrous oxide is completely breathed out of the body within 30 minutes of the end of the treatment. This means that the child can recover very quickly from this type of sedation.

How to prepare your child
Before the treatment, the child in your care can eat normally but with only a light meal being taken up to 2 hours before the treatment. Please give the child any routine medicines as normal. Any medicines or inhalers that the child may need should be brought to the dental treatment appointment.

Written consent will be required from the parent/carer before any treatment can be given to the child. If you have agreed and signed the consent form at the assessment appointment, and you are then unable to attend on the day of the treatment, the child must be accompanied by a responsible adult (over 18 years of age).

The child should wear loose, comfortable clothing. No valuables should be brought to the appointment.

If the child is unwell on the day with cold/flu symptoms or any contagious illness, please contact the dentist for advice. The appointment may need to be rearranged.

What to expect
It is usual to have two or more appointments. At the first appointment (assessment), the dentist will take a full dental history of the child. Various methods of providing the dental treatment with or without sedation will be explained. Other than in an emergency, the treatment will take place at the second or subsequent appointments.

If it is agreed that dental treatment with inhalation sedation is the best way to treat the child, then the dentist will confirm the child’s medical history. If further information is required, the child’s general medical practitioner or specialist will be contacted.
Please avoid bringing other children with you on the day of treatment.

**What will happen during the sedation?**

During the procedure, the child will breathe the nitrous oxide and oxygen through a nosepiece on the nose. The child may feel warm with tingly fingers and toes.

Once the child is sedated, and feels drowsy and relaxed, the dentist can use local anaesthesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections that the child may need can then be given through this numbed area to reduce the chance of any discomfort.

When the dental treatment is completed, the nitrous oxide mixture will be stopped and replaced with oxygen. The nosepiece will be taken off, and the child will be sat up in the dentist’s chair and will continue to recover fully for a few minutes. The dentist or a member of the dental team will monitor the child during recovery.

The child will be able to leave the surgery/dental practice once he or she has fully recovered, is alert and is not feeling dizzy. This usually takes about 30 minutes after the treatment has ended. The child will be checked by the dentist before being allowed to go home.

The child may not participate in organised or active sports for the rest of the day but may be able to return to school. The dentist will discuss this with you.

The child can eat and drink normally after the treatment but care should be taken if areas of the mouth are still numb to avoid lip, cheek or tongue biting. You will be given information relating to any local analgesia and the treatment the child has received. The dentist will explain which pain relief medicines the child may have while recovering and the local analgesia wears off.

You will be given a telephone number of who to contact in case of any concerns.
Hello! I am Fluffy the Bear.

Last week I had magic air sedation and had my tooth fixed at the dentist.

The dentist is someone who helps look after my teeth. I see them in a dental surgery.

Magic air helps make fixing my teeth easy.

Getting ready

When I saw my dentist, I sat in a chair and the dentist looked at my teeth with a small mirror. My tooth had a hole in it and the dentist took a photograph (called an x-ray) of it to see it better.

The dentist said that I needed the hole to be fixed or my tooth would start to hurt. To make fixing it easy, I could have magic air.

The day I had my tooth fixed

Before I had magic air, I had breakfast but I did not eat too much.

I sat in the dentist chair, and the dentist and the dentist’s nurse showed me a mask to wear on my nose. The mask looked like an airline pilot’s mask and I could hold it on my nose.

So that it didn’t fall off my nose, the dentist laid the back of the chair down so I was lying flat. Tubes were attached to the nosepiece to let the magic air go through them.
I practised breathing through my nose with fresh air first. It didn’t smell of anything. The dentist counted my teeth with the mirror.

Before I knew it, I felt warm and my fingers and toes felt all tingly. I felt a bit like I was flying. The dentist and the nurse talked to me while I had the magic air.

**Having my tooth fixed**

The dentist dried my tooth with cotton wool and washed my tooth with numbing liquid. My tooth felt all tingly, fuzzy and numb.

The dentist cleaned my tooth with an electric toothbrush that squirted water and made a buzzy sound. I had a filling put in the hole. The dentist and nurse held a light over my tooth to make the filling hard and strong.

I breathed the magic air through my nosepiece. I felt nice while my tooth was fixed.

When my tooth was mended, I started to feel less tingly and the floaty feeling began to go away.

**Afterwards**

The dentist sat the chair up gently and took off the nosepiece. My head felt a bit dizzy but it was alright.

After 5 minutes, the dizzy feeling had gone, and I sat in the waiting room and played for a little while. My tooth still felt tingly and numb, and the dentist told me not to bite my lip while it still felt funny. I then went home and played quietly.

My tooth stopped feeling tingly after I left the dentist and now it feels good because I don’t have a hole anymore.
Example 12:

Intravenous sedation: Parents or those with parental responsibility for children and young people aged under 16 years

What is intravenous sedation?
The child in your care may require intravenous sedation for dental treatment. The use of a sedative drug (medicine) makes the child drowsy and relaxed and less aware of the treatment. The patient will often have few memories of what has happened during the treatment. Intravenous sedation does not make your child unconscious.

Intravenous sedation is usually given by using a single drug called midazolam. A dose, determined for your child individually, will be given into a vein in the back of the hand or arm using a cannula (a thin flexible tube). A needle is used to put the cannula into the vein and the needle is then removed straight away. Once the cannula is in the vein, the sedation drug can be given without using any more needles. The cannula remains in until the dentist has checked that you child has recovered but it will be removed before going home.

A cream containing local anaesthetic may be used to make the injection site numb before the cannula is inserted. You may be asked to put this cream on the child’s hand or arm before you leave home. This allows enough time for it to work properly before having the sedation medicine.

Benefits and risks of intravenous sedation
Intravenous sedation is used to reduce anxiety and fear of dental treatment. This makes children more co-operative when having dental treatment. It is particularly helpful if children are having a long, uncomfortable or more complicated procedure.

The dentist and members of the dental team are trained to give sedation. They watch the child closely and treat any problems that may develop. They are required to use appropriate monitoring equipment during sedation. The child will go to a recovery area after the treatment where he or she will be observed until having made a full recovery from the sedation.

It is a widely used technique but, as with the administration of any medicines, there are risks associated with intravenous sedation. Risks include:

• A reduction of oxygen in the blood stream due to poor breathing during sedation. The child may be asked by the dentist/sedationist to take deep breaths to correct this. The dentist/sedationist will continually monitor the child’s breathing and oxygen levels throughout the procedure.
• Bruising at the site of the cannula. This may take several days to fade completely.

Very rare risks are allergic reactions to the sedative drugs your child has been given or vomiting during the procedure. The dentist/sedationist will discuss any concerns that you may have about the child prior to the procedure taking place.

What to expect
The various methods of dental treatment planned for the child will be discussed with you at an assessment appointment following a full dental examination. The dental treatment planned will then take place at a second or subsequent appointment. In an emergency, the treatment may be carried out on the same day as assessment.

If it is agreed that intravenous sedation is the best way to treat the child, then the dentist will confirm:

• The child’s height and weight
• The child’s blood pressure – taken with a cuff on the child’s arm. This may not happen for young children.
• The level of oxygen in the blood – taken with a simple clip on
the child’s finger
• The child’s medical history. If further information is required at this stage, the child’s general medical practitioner or specialist will be contacted.

If you have any questions or are unsure about the sedation planned for the child, do not hesitate to ask the dentist.

**How to prepare your child**
The dentist will discuss with you and explain what the child is able to eat and drink prior to the appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

Written consent will be required from the parent/carer before any treatment can be given to the child. If you have agreed and signed the consent form at the assessment appointment and you are then unable to attend with the child on the day of treatment, the child must be accompanied by a responsible adult (over 18 years of age).

Please give any routine medicines as normal. Any medicines or inhalers that the child may need should be brought with you to the appointment.

Dress your child in loose, comfortable clothing. No valuables should be brought to the appointment.

If the child is unwell on the day of treatment with cold/flu symptoms or any contagious illness, please contact the dentist for advice.

The appointment may need to be rearranged.

Please avoid bringing other children with you on the day of treatment.

**What will happen?**
The child will be monitored during the procedure. This will include measurements of blood pressure, heart rate and oxygen levels at regular intervals.

Once the child is sedated, and feels drowsy and relaxed, the dentist can use local analgesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections that the child may need can then be given through this numbed area to reduce the chance of any discomfort.

After the treatment has finished, the child will spend some time in the recovery area and will not be allowed to go home until alert and responsive. The dentist will check the patient before he or she is allowed to go home.

The child may not return to school and should not participate in active sports for the rest of the day. You may wish to make plans about how best to travel home with the child following the treatment.

The child must be supervised by a responsible adult for the rest of the day. Arrangements may need to be made for the care of other children or elderly dependent relatives during this time.

Children can be sleepy, upset or agitated for up to 3 hours after the treatment. They will, however, have little memory of the procedure. Occasionally, children feel a bit sick or may get hiccups. There may be some bruising on the hand or arm where the sedative medicine was given. You will be given information relating to any local analgesia and the treatment the child has received. The dental team will advise you about any medicines the child may need while recovering from the treatment. You will be given a telephone number of who to contact in case of any concerns.
Example 13:
Intravenous sedation:
Young people aged 12–16 years

What is intravenous sedation?
This is when you receive a drug to sedate you while you have your dental treatment. The drug makes you feel sleepy and relaxed but you will not be unconscious. It is given by your dentist, or by another dentist or a doctor.

Why should I have intravenous sedation?
Having sedation this way helps reduce any worry or anxiety you have about having your teeth treated. It can also help if you need a very long procedure or a painful procedure, such as having a tooth out.

Consent
The information provided here is a general guide for all patients having intravenous sedation. Your dentist will discuss with you your specific treatment plan and some of the advice described might not be relevant to the treatment you are going to have.

Nothing will happen until you and your parent or guardian understand and agree what has been planned for you. You will be able to discuss the treatment with your dentist. Your parent or guardian will need to be with you on the day of the treatment to sign the consent form, even if it was signed at an assessment visit.

Getting ready for your sedation
Before you have intravenous sedation, the dentist will ask you about your general health. If you have any long-term medical problems, the dentist will discuss these with you and your parent or guardian. The dentist will have also checked your height, weight, blood pressure (taken with a cuff that wraps around your arm) and oxygen levels in your blood, using a clip that attaches to your finger.

On the day of the treatment, you should take any regular medicines and bring your medicines or inhalers with you.

If you have a cold or feel unwell, you or your parent/guardian will need to tell the dentist as you need to be as healthy as possible on the day of treatment.

If you think you may be pregnant, you need to let the dentist know. You may need to come back to have your treatment at another time.

Leave all jewellery and valuables at home. Do not wear excessive make up or any nail polish to the appointment. These can interfere with the monitoring equipment that is used while you are sedated.

Getting ready for your sedation
Before you have intravenous sedation, the dentist will ask you about your general health. If you have any long-term medical problems, the dentist will discuss these with you and your parent or guardian. The dentist will have also checked your height, weight, blood pressure (taken with a cuff that wraps around your arm) and oxygen levels in your blood, using a clip that attaches to your finger.

On the day of the treatment, you should take any regular medicines and bring your medicines or inhalers with you.

If you have a cold or feel unwell, you or your parent/guardian will need to tell the dentist as you need to be as healthy as possible on the day of treatment.

If you think you may be pregnant, you need to let the dentist know. You may need to come back to have your treatment at another time.

Leave all jewellery and valuables at home. Do not wear excessive make up or any nail polish to the appointment. These can interfere with the monitoring equipment that is used while you are sedated.

Your dentist will discuss with you and explain what you are able to eat and drink prior to your appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

You will be asked to turn off your mobile phone during the appointment.

Clothing
Wear loose, comfortable clothing and flat shoes. If you wear contact lenses, you may need to remove them. You may need to bring your glasses or spare lenses to wear after the appointment.

Having the intravenous sedation
Your dentist or a member of the dental team may put an anaesthetic cream on the back of your hand or on your arm about 45–60 minutes before the appointment. You may be asked to do this at home, before you come to the dental surgery.

The cream makes the skin on your hand or arm go numb. The dentist (or doctor who will be helping with the sedation) will then place a cannula in a vein in your hand or arm. A cannula is a thin flexible tube. A needle is used to put the cannula in. The needle is then removed straight away but
the cannula stays inside the vein. The anaesthetic cream placed on the hand or arm helps reduce the discomfort of having the cannula inserted.

Once the cannula is in the vein, the sedation drug can be injected through it without using any more needles. The cannula is left in until the dentist (or doctor) allows you to go home. He or she will check that you have recovered properly from the sedation before letting you leave the dental surgery.

Your parent or guardian will be with you until the sedative drug is given and will then usually wait for you outside the surgery while your teeth are treated.

**While you are sedated and having your dental treatment**

Once you are sedated, and feel drowsy and relaxed, the dentist can use local analgesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections that you may need can then be given through this numbed area to reduce the chance of any discomfort.

A small clip will be put on your finger to measure your heart rate and the level of oxygen in your blood. Your blood pressure will be taken while you are sedated.

**How will I feel?**

You will feel drowsy and sleepy during the treatment. Afterwards you may not remember very much about the treatment.

**Afterwards**

You may be moved to another area to recover fully. The dental team will decide when it is safe for you to go home. You will need to rest at home. You cannot go home on your own – your parent, guardian or other responsible adult will need to stay with you for the rest of the day.

You may feel sick or drowsy. You may have a bruise where the cannula was. Your mouth may still feel numb or tingly for up to 3 hours. You will need to be careful not to bite your lip or cheek while it is numb.

You will need to avoid any strenuous exercise like riding a bike, driving a car or motorbike, playing active sports or training until at least the following day. Sometimes you may need to avoid these things for 24 hours but your dentist will advise you.

You should be careful about what you write or text on social media after your treatment as you may be a bit muddled and lack judgement.

**Are there any risks to intravenous sedation I should know about?**

Intravenous sedation is widely used but, as with taking any medicines, there are risks. Your dentist and members of the dental team are trained to give sedation. They watch you closely and treat any problems that may develop.

The key risks are:

- A reduction of oxygen in the blood stream due to poor breathing during sedation. You may be asked by the dentist/sedationist to take deep breaths to correct this. Your breathing and oxygen levels will be monitored throughout the procedure.

  - Bruising at the site of the cannula. This may take several days to fade completely.

Very rare risks are allergic reactions to the sedative drugs that you have been given or vomiting during the procedure. Your dentist/sedationist will discuss any concerns that you may have prior to the procedure taking place.

Before you are discharged, you will be given information about pain relief as well as how and when to take any prescription medicines. You will be given information relating to any local analgesia and the treatment you have received. You or your parent/guardian will be given a telephone number of who to contact if you have any concerns.
Example 14: Oral sedation: Parents or those with parental responsibility for children and young people aged under 16 years

What is oral sedation?
The child in your care may require oral sedation for dental treatment. The use of a sedative drug (medicine) makes the child drowsy, less aware of what is happening and with few memories of what has happened during the treatment. Oral sedation does not make your child unconscious.

Oral sedation is usually given as a single drug called midazolam. A dose, chosen for your child individually, will be given as a drink or as a syrup. The sedation usually takes 20 minutes to take effect.

Once the child is sedated (drowsy), a needle is used to place a cannula (small plastic tube) into a vein in the back of the hand or in the arm. This allows a drug to be given that reverses the effect of the sedation, if necessary. A cream containing local anaesthetic will be used on the back of the hand to numb the area, before this cannula is placed. You may be asked to apply this cream to the child before coming to the dental surgery.

Benefits and risks of oral sedation
Oral sedation is used to reduce anxiety and fear of dental treatment. This usually makes children more co-operative when having treatment. It is particularly helpful if children are having a long, uncomfortable or more complicated procedure.

Very rare risks are allergic reactions to the sedative drugs that your child has been given or vomiting during the procedure. Your dentist/sedationist will discuss any concerns that you may have about the child prior to the procedure taking place.

An oxygen supply will be available and oxygen will be given if necessary. There is also a risk that the child may not like the feeling of sedation and become tearful, in which case the sedation may be stopped.

What to expect
The various methods of dental treatment planned for the child will be discussed with you at a separate assessment appointment following a full dental examination. In exceptional circumstances, treatment may be carried out on the same day as assessment.

Before the sedation can be given, the dentist will confirm:

- The child’s height and weight
- The child’s blood pressure – taken with a cuff on the child’s arm. This may not happen for young children.
- The level of oxygen in the
blood – taken with a simple clip on the child’s finger

- The child’s medical history. If further information is required at this stage, the child’s general medical practitioner or specialist will be contacted.

If you have any questions or are unclear about the sedation planned for the child, do not hesitate to ask your dentist.

**How to prepare your child**
The dentist will discuss with you and explain what the patient is able to eat and drink prior to the appointment. You will also be given this information in writing. It is important that these instructions are followed carefully.

Written consent will be required from the person with parental responsibility/carer before any treatment can be given to the child. If you have agreed and signed the consent form at the assessment appointment and you are then unable to attend with the child on the day of treatment, the child must be accompanied by a responsible adult (over 18 years of age).

Please give routine medicines as normal. Any medicines or inhalers that the child may need should be brought with you to the appointment.

Dress your child in loose, comfortable clothing. No valuables should be brought to the appointment.

If the child is unwell on the day with cold/flu symptoms or any contagious illness, please contact the dentist for advice.

The appointment may need to be rearranged.

Please avoid bringing other children with you on the day of treatment

**What will happen?**
The child will be monitored during the procedure. This will include measurements of blood pressure, heart rate and oxygen levels at regular intervals.

Once the child is sedated, and feels drowsy and relaxed, the dentist can use local analgesia (pain relief that numbs the site of the dental treatment). Local anaesthetic as a paste is sometimes used to numb the site of the treatment. Any injections that the child may need can then be given through this numbed area to reduce the chance of any discomfort.

After the treatment has finished, the child will spend some time in the recovery area until alert and responsive. He or she will be checked by the dentist before being allowed to go home.

The child may not return to school and should not participate in active sports for the rest of the day. You may wish to make plans about how best to travel home with the child following the treatment.

The child must be supervised by a responsible adult for the rest of the day. Arrangements may need to be made for the care of other children or elderly dependent relatives during this time.

Children can be sleepy, upset or agitated for up to 3 hours after treatment. They will, however, have little memory of the procedure. Occasionally, they get hiccups. There may be some bruising on the hand or arm where the cannula was inserted.

You will be given information relating to any local analgesia and the treatment the child has received. The dental team will advise you about any medicines the child may need while recovering from the treatment.

You will be given a telephone number of who to contact in case of any concerns.
Example 15:
Dental filling: Pictorial sequence for young children

Meet the dentist

Have teeth cleaned

Sit in dentist chair

Have filling put in tooth

Lie down

Bite down on filling

Dentist checks teeth

Wait until I stop feeling fuzzy

Try on nosepiece

Sit up

Feel nice with happy air

Say goodbye

The design and artwork of Dr Charlotte Curl are gratefully acknowledged.
Appendix 4: Frequently asked questions

1. Why were the new IACSD standards necessary?
2. When do the new standards become effective?
3. I am an experienced provider of conscious sedation. Do I need to re-train or undertake a postgraduate certificate or diploma in conscious sedation?
4. Must all sedation courses now be accredited?
5. How do I apply for course accreditation?
6. I enrolled on a training course prior to April 22 2015 and I am currently completing my mentored cases. Will I be compliant with the new guidelines?
7. I have been on the DSTG list of mentors for many years and have successfully mentored a number of dentists learning to use conscious sedation. Must I now stop doing this?
8. Does sedation carried out as part of DCT2 training satisfy the requirements for conscious sedation training?
9. May new DF3’s provide IV and inhalational sedation under appropriate supervision?
10. I have over 25 years of experience using IVS but now carry out less than one case per month. Should I continue?
11. I am intending to employ a GMP colleague to provide sedation in my practice – must he undertake training in dental sedation?
12. What training does the 'second appropriate person' now require?
13. Is it possible to gain a qualification in dental nursing for IS alone?
14. When will registered Dental Nurses be obliged to have the NEBDN Certificate in Dental Sedation Nursing?
15. I have two dental nurses. Does the chairside nurse need to be sedation-trained?
16. What level of life support training does the sedation team need?
17. Can I continue to provide IS whilst waiting to attend an immediate life support course?
18. How can I demonstrate that my practice facilities are equivalent to those of an ‘NHS Acute Trust in England’?
19. How can I find out more about the SAAD Safe Sedation Practice Scheme?
20. How can I show that I have ‘skills equivalent to those expected of a specialist/consultant in paediatric dentistry’?
21. How can I show that I have ‘skills equivalent to those expected of a consultant in anaesthesia competent in sedation for dentistry’?
22. I have been asked to provide IVS at another dental practice. I have many years of experience but no formal qualification in sedation. Is this permitted?
23. May a Dental Therapist or Hygienist provide inhalational sedation without a dentist being on the premises?
24. When should I take an adult patient’s blood pressure during IVS?
25. Should I consider buying a capnograph for my IVS service?
26. May I use the IACSD information leaflets in my practice?
1. Why were the new IACSD standards necessary?
The new standards respond to changes in sedation practice and in the requirements for education, training and its validation. There was also an appreciation that common standards needed to be applied to the use of conscious sedation by everyone in the healthcare team - dentists, doctors, nurses and other DCPs. The new standards were agreed by a wide range of organisations including the Dental Faculties of the surgical Royal Colleges, the Royal College of Anaesthetists and specialist societies.

2. When do the new standards become effective?
From the date of publication of the report on 22 April 2015.

3. I am an experienced provider of conscious sedation. Do I need to re-train or undertake a postgraduate certificate or diploma in conscious sedation?
Experienced sedation practitioners are covered by the Transitional Arrangements but you must comply with the standards in all other sections of the report. A postgraduate sedation qualification is not mandatory.

4. Must all sedation courses now be accredited?
All courses intended for practitioners who wish to undertake training in a sedation technique that leads to independent clinical practice must now include supervised clinical training and have external validation. UK university-based courses and those run by Postgraduate Deaneries are compliant. Other courses which lead to independent practice, including those run by private providers, must be accredited by STAC (Sedation Training Accreditation Committee). CPD and ‘update’ courses offering only knowledge and skills training do not need external accreditation.

5. How do I apply for course accreditation?
You should contact Neil Sutcliffe at FDS RCS Eng (stac@rcseng.ac.uk) for information about the accreditation process.

6. I enrolled on a training course prior to April 22 2015 and I am currently completing my mentored cases. Will I be compliant with the new guidelines?
Yes, you are compliant with the spirit of the IACSD standards. When you have completed your training you will then be covered by the Transitional Arrangements.

7. I have been on the DSTG list of mentors for many years and have successfully mentored a number of dentists learning to use conscious sedation. Must I now stop doing this?
The STAC (Sedation Training Accreditation Committee) is able to accredit “sedation supervisors” (see above).

8. Does sedation carried out as part of DCT2 training satisfy the requirements for conscious sedation training?
Training provided by a Deanery or a University does not need to be accredited, but to reach the level of independent practice, the training provided should follow the standards as set out in the IACSD Report. All sedation experience will be useful and should be recorded in your clinical logbook.
9. May new DF3s provide IV and inhalational sedation under appropriate supervision?
Yes, they may. However this will not allow them to undertake independent clinical practice using these techniques once DF3 is completed, unless the DF3 training programme meets the requirements set out in the IACSD standards.

10. I have over 25 years of experience using IVS but now carry out less than one case per month. Should I continue?
This is a matter for you to decide, perhaps in consultation with your professional indemnity organisation. As an experienced practitioner you are covered by the Transitional Arrangements but carrying out only one case per month may not be considered sufficient for maintaining competence. You should also consider the IACSD CPD requirements.

11. I am intending to employ a GMP colleague to provide sedation in my practice – must he undertake training in dental sedation?
Yes, the new guidance applies to doctors and dentists. Your colleague must acquire knowledge, skills and supervised clinical experience before providing sedation in your practice. Training opportunities are currently more limited for doctors than dentists.

12. What training does the ‘second appropriate person’ now require?
Dental Nurses must be trained and experienced but, like dentists, are covered by the Transitional Arrangements. The NEBDN Certificate in Conscious Sedation Nursing is recommended but not mandatory.

13. Is it possible to gain a qualification in dental nursing for IS alone?
We understand that NEBDN is considering offering this but do not know the timescale. You should contact either NEBDN or your local Dental Deanery for availability of courses.

14. When will registered Dental Nurses be obliged to have the NEBDN Certificate in Dental Sedation Nursing?
There are no plans to make this qualification compulsory. However, all Dental Nurses should be encouraged to work towards it.

15. I have two dental nurses. Does the chairside nurse need to be sedation-trained?
No, as long the sedation-trained nurse is appropriately trained and experienced and remains in the surgery throughout the procedure. However, it might offer greater flexibility if both nurses were sedation-trained.

16. What level of life support training does the sedation team need?
Practitioners must be able to provide age-appropriate Immediate Life Support as defined by the main elements of the Resuscitation Council (UK) ILS and PILS training programmes. It is not essential to undertake a Resuscitation Council (UK) accredited ILS/PILS course. Alternative courses with equivalent content which are adapted to the needs of dental practice are acceptable: these might also include the management of common sedation, medical and dental emergencies.

17. Can I continue to provide IS whilst waiting to attend an immediate life support course?
All dentists should have current Immediate Life Support skills. You should contact your professional indemnity organisation for advice.
18. How can I demonstrate that my practice facilities are equivalent to those of an ‘NHS Acute Trust in England’?
You must be able to provide evidence that in the event of a patient collapse you have the knowledge, skills and facilities to offer the same quality of immediate care as would be expected in an NHS Acute Trust. Evidence might include written protocols for managing collapse and adverse reactions, the timely transfer of a collapsed patient to a hospital with appropriate resuscitation facilities and the regular checking of emergency drugs and equipment. Current Immediate Life Support certificates and records of regular team-based participation in real-time emergency scenarios would also be appropriate. The SAAD Safe Sedation Practice Scheme (www.saad.org.uk) covers some of these elements. The checklist used by SAAD inspectors is available for download and may be used for self-assessment. It is not the responsibility of IACSD to assess evidence.

19. How can I find out more about the SAAD Safe Sedation Practice Scheme?
You should contact the Executive Secretary at SAAD at www.saad.org.uk.

20. How can I show that I have ‘skills equivalent to those expected of a specialist/consultant in paediatric dentistry’?
You must be able to provide evidence that the person leading the team possesses the knowledge and skills which will ensure that treatment planning and care under conscious sedation will be delivered to the same standard as would be expected of a specialist. Evidence might include training (including CPD, postgraduate qualifications, clinical attachments, honorary NHS appointments etc.) and documented experience appropriate to the age group/s to be treated. A good record of experience would include dated (but anonymised) patient data including age, ASA status, sedation technique, monitoring, dental treatment, recovery, outcome, adverse incidents and a summary of the number of sedation cases managed per year. The training and experience of other members of the sedation team, any support available from a local peer, consultant or MCN and the equipment and facilities available might also be relevant. The SAAD Safe Sedation Practice Scheme covers some of these elements. The checklist used by SAAD inspectors is available for download and may be used for self-assessment. Written support from specialist/consultant who is familiar with your experience might also be helpful. The syllabuses in Appendix 1 define the knowledge and skills required of the whole team for a variety of techniques and age groups.

21. How can I show that I have ‘skills equivalent to those expected of a consultant in anaesthesia competent in sedation for dentistry’?
If you are an anaesthetist (i.e. on the GMC Specialist Register in anaesthetics) wishing to commence providing dental conscious sedation for children and young people you must be able to demonstrate training and experience in paediatric anaesthesia to a standard equivalent to that detailed in the paediatric section of the RCoA curriculum and acquisition of the competencies outlined in the RCoA dental sedation curriculum (IACSD Reference 34).

If you are an anaesthetist already engaged in the provision of dental conscious sedation for children and young people you must be able to demonstrate that you possess the necessary competencies for safe independent sedation practice. Formal appraisal/revalidation for this activity would include demonstration of appropriate paediatric anaesthetic training and experience, possession of the necessary paediatric dental sedation competencies (IACSD Reference 34), ongoing experience (logbook of sedation activity), evidence of appropriate continuing professional development, participation in audit of practice and outcomes and documentation of any complaints.
If you are a medical or dental practitioner you must be able to provide evidence that you possess the knowledge and skills which will ensure that conscious sedation will be delivered to the same standard as would be expected of a specialist in anaesthesia (see above) who is competent in sedation for dentistry. This includes competence in age-appropriate ‘rescue’ procedures in the event of cardio-respiratory complications associated with a deeper level of sedation than intended. However, you are not expected to possess broader anaesthetic skills which are not directly relevant to the administration of dental conscious sedation or its complications. Evidence might include formal appraisal/revalidation, training (including CPD, postgraduate qualifications, clinical attachments, honorary NHS appointments etc.) and documented experience appropriate to the age group/s to be treated. A satisfactory record of experience would include dated (but anonymised) patient data including age, ASA status, sedation technique, monitoring, dental treatment, recovery, outcome, adverse incidents and a summary of the number of sedation cases managed per year. The training and experience of other members of the sedation team, support available from a local peer, specialist anaesthetist or MCN and the equipment and facilities available might also be relevant. The SAAD Safe Sedation Practice Scheme covers some of these elements. The checklist used by SAAD inspectors is available for download and may be used for self-assessment. Written support from a specialist anaesthetist who is familiar with your experience might also be helpful. The syllabuses in Appendix 1 define the knowledge and skills required of the whole team for a variety of techniques and age groups.

22. I have been asked to provide IVS at another dental practice. I have many years of experience but no formal qualification in sedation. Is this permitted?
Yes, you are covered by the ‘Transitional Arrangements’ but you must comply with all other sections of the IACSD document.

23. May a Dental Therapist or Hygienist provide inhalational sedation without a dentist being on the premises?
Yes, as long as the Dental Therapist or Hygienist is supported by an appropriately trained and experienced Dental Nurse (‘second appropriate person’).

24. When should I take an adult patient’s blood pressure during IVS?
NIBP should be performed before and after sedation and at ‘appropriate intervals’ during the procedure. The intervals are determined following individual patient assessment.

25. Should I consider buying a capnograph for my IVS service?
Capnography is not currently recommended for routine use in fit dental patients. However, it detects hypoventilation sooner than pulse oximetry and so it is likely to become more widely used, especially for medically compromised patients.

26. May I use the IACSD information leaflets in my practice?
Yes, you may use them unchanged as long as you acknowledge the Dental Faculties of the surgical Royal Colleges and the Royal College of Anaesthetists. The information leaflets are for guidance in good practice and if you wish to amend the leaflets for your local requirements, then they must not display the logo of any of the Royal Colleges.
